*****************************************************************************************************/

bVision/LibVision
ION

 'LibVision' components (#define, structures and functions) begin with VIS to avoid
on with any other modules.

e values in the header files may need to be changed. The values in the program source
ed on the values in the header and should not be changed.

********* *
ne values *
********* *

 default informations
---------------------
ne VIS_MSB         5   : Number of most significant bits used for the 3D tables
ne VIS_NONE        0   : No colour class
ne VIS_CONFLICT    255 : Colour-conflict class
ne VIS_SAT_THRES   32  : Threshold for limit saturation
alues are coded on 8 bits, but for a RGB 3D space, ((2^8)^3)=16MB...
SB defines how many MSB should be used : as an exemple for VIS_MSB=5 -> ((2^5)^3)=32kB.
ONE and VIS_CONFLICT define the two defaults values for the no-colour class and the colour-conflict

AT_THRES defines the default saturation threshold to define colours within the RGB space avoiding
g white shades as colours.

s for the algorithm
--------------------
ne VIS_ALGO_DEPTH 1                : One pixel around
ne VIS_ALGO_FAST  1                : Use fast
ne VIS_ALGO_STEP  2                : Every 2nd pixel
ne VIS_ALGO_LOOP  (VIS_ALGO_STEP-1) : defined internally (in LibVision.c)
 values define the way to process the image. Some function are optimised for certain parameters.
e VIS_Algo structure for more informations on these values.

ize information
---------------
ne VIS_IMROW imagerows    : number of rows
ne VIS_IMCOL imagecolumns : number of columns
 two values are used to avoid the ANSI C warning about variable-size variables definition.

 number of classes to be processed
----------------------------------
ne VIS_MAX_CLASS 10 : No more than 10 different classes
value is used to avoid the ANSI C warning about variable-size variables definition.
nes the maximum number of colour classes to be processed by the library.

play informations, used by VIS_ComputeBW
-----------------------------------------
ne VIS_LCD_DISPLAY_ROW  64
ne VIS_LCD_DISPLAY_COL  128
ne VIS_LCD_DISPLAY_SIZE ((VIS_LCD_DISPLAY_ROW*VIS_LCD_DISPLAY_COL)>>3)
 values are used to define the LCD display properties. The VIS_LCD_DISPLAY_SIZE defines the 1D
length of a complete B/W image for the LCD display.

hm information, ONLY depending on VIS_MSB in the .h, (declared in LibVision.c)
-------------------------------------------------------------------------------
ne VIS_LSB      (8-VIS_MSB)  : Less significant bits
ne VIS_VALUES   (1<<VIS_MSB) : Number of intervals
ne VIS_SHIFT    (1<<VIS_LSB) : Shift for loops
 values are used internally and are based on the VIS_MSB value. They are used to define internal
to deal with the RGB 3D colour space.

es lookup tables : normal table, border table, angle tables
------------------------------------------------------------
ne VIS_ROW    0
ne VIS_COL    1
ne VIS_ALPHA  0
ne VIS_BETA   1
ne VIS_NORMAL 0
ne VIS_BORDER 1
 values are used internally to access the right part of the distance tables.
e VIS_DistanceTables for more informations.

************* *
ef structures *
************* *

ce
--
ef BYTE VIS_RGBSpace[1<<VIS_MSB][1<<VIS_MSB][1<<VIS_MSB];
ition of a RGB 3D colour space type. Each dimension is depending on the number of MSB used.

Hue conversion table
ef BYTE VIS_HueTable[1<<VIS_MSB][1<<VIS_MSB][1<<VIS_MSB];
ition of a RGB->Hue 3D conversion table. Each dimension is depending on the number of MSB used.

hue and automatic range structure
---------------------------------
*   typedef struct {
*     int Hue;   : Median hue value
*     int Range; : Range around the median value
* } VIS_DefineHue;
* @ Used to get the 'median hue' and the 'hue range' from the function 'VIS_MedianHue'.
*
* Image processing struct : table -> undenoised class, index, X and Y_list denoised data
* ---------------------------------------------------------------------------------------
*   typedef struct {
*     BYTE *table;  : Binary table
*     BYTE *X_list; : X positions list
*     BYTE *Y_list; : Y positions list
*     int  index;   : Number of elements in X_list and Y_list
*   } VIS_Process;
* @ The VIS_Process structure is used internally and contains a binary picture (table) of the colour-class,
* a pixel list of the denoised binary picture (X and Y list) and the number of pixel in these lists (index).
* 'index' is used to look for the limit pixels of the object in the denoised pixel lists.
*
* Algorithm options struct
* ------------------------
*   typedef struct {
*     BYTE depth; : denoise one dot around
*     BYTE fast;  : use fast algorithm, only for depth=1
*     BYTE step;  : process every dots or two dots only
*     BYTE loop;  : shift for loops, modified internally loop=step-1
*   } VIS_Algo;
* @ These values enable to choose between several optimised functions for image processing.
* 'depth' indicates on how many pixels the "erosion" is applied.
* 'fast'  indicates the use of an easier loop if the "erosion" is applied on only 1 pixel (depth==1).
* 'step'  is either every pixels or every second pixels.
* 'loop'  is used internally to define a shift value depending on 'step'.
*
* Object structure : class and limits
* -----------------------------------
*   typedef struct {
*     BYTE class;                : Class number of the object
*     BYTE top, bot, right, left; : Coordinates of the found object
*   } VIS_Object;
* @ This structure is created by the user to get back the result. If an object has been found, 'class' will
* contain the class number, i.e. VIS_NONE if no object from the current colour has been found.
* 'top', 'bot', 'right' and 'left' contain the pixel limits of the found object in the image.
*
* Camera angles and positions offsets to calibrate
* ------------------------------------------------
*   typedef struct {
*     int   alpha;  : Servo alpha offset
*     int   height; : Camera height
*     int   lenght; : Camera distance to the front of the robot
*     float angle;  : Lens angle in radians
*     float beta;   : Camera beta offset
*   } VIS_CameraOffset;
* @ This structure defines the camera properties and position.
* 'alpha'  gives the servo position when the camera looks straight forward,
* 'beta'   gives the angle offset between the camera middle axis and the horizontal axis,
* 'lenght' gives the distance offset from the camera to the robot front,
* 'height' gives the camera heigth to the ground,
* 'angle'  defines the camera view angle.
* @ These values are used to calibrate the ball distance to the camera and the angle positions.
*
* Camera offset default informations
* ----------------------------------
*   static const int   VIS_CAM_HEIGHT[2][5]={{-1, -1, -1, -1, -1}, {-1, -1, -1, -1, -1}};
*   static const int   VIS_CAM_LENGHT[2][5]={{-1, -1, -1, -1, -1}, {-1, -1, -1, -1, -1}};
*   static const BYTE  VIS_CAM_ALPHA[2][5]={{-1, -1, -1, -1, -1}, {-1, -1, -1, -1, -1}};
*   static const float VIS_CAM_BETA[2][5]={{-1, -1, -1, -1, -1}, {-1, -1, -1, -1, -1}};
*   static const float VIS_CAM_ANGLE[2][5]={{0.85, 0.85, 0.85, 0.85, 0.85}, {0.85, 0.85, 0.85, 0.85, 0.85}};
* @ These values are used as defaults for the camera calibration (VIS_CameraOffset).
* @ Angles informations have to be set up in radians.
*
* Distances lookup tables : normal table, border table, angle tables
* ------------------------------------------------------------------
*   typedef struct {
*     short Dist_dist[2][imagerows][imagecolumns];     : Direct relative distance, border or normal
*     short Dist_coord[2][2][imagerows][imagecolumns]; : Relative distance in x and y, border or normal
*     float Dist_angle[2][imagerows][imagecolumns];    : Alpha and beta angles
*   } VIS_DistanceTables;
* @ This structure defines the distance table and is a global variable.
* 'dist'  defines the direct distance between the robot and the ball,
* 'coord' defines the side and depth coordinates of the ball compared to the camera,
* 'angle' defines the object angle position compared to the camera.
*
* Distance structure
* ------------------
*   typedef struct {
*     short d_row; : depth distance
*     short d_col; : side distance
*     short dist;  : direct distance : dist^2=d_row^2+d_col^2
*     float alpha; : sideways angle
*     float beta;  : up-down angle
*   } VIS_Distance;
* @ The distance structure is for the user to get the ball position using VIS_GetPosition.
* @ The distance is only valid for the ball, but the angle position can be used for any object.
*
* * ************************************** *
* * Global variables (defined in LibVision.c) *
* * ************************************** *
*
*   VIS_HueTable       HueTable;       : Global hue-table conversion
*   BYTE               HueTableOK=0;   : Flag if hue-table is initialised or not
*   VIS_Algo           AlgoInfo;       : Global algorithm information
*   BYTE               AlgoInfoOK=0;   : Flag if the algorithm informations are initialised or not
*   VIS_CameraOffset   CamInfo;        : Camera setup for distance
*   BYTE               CamInfoOK=0;    : Flag of the camera informations are initialised or not
*   VIS_DistanceTables DistTables;     : Distance tables
```

```
            DistTablesOK=0; : Flag if the distance tables are initialised or not
 are the global variables declared in the LibVision.c program. They are the basic informations the
 needs to work.
