$$I_0(x) = \sum_{k=0}^{\infty} \frac{(x^2/4)^k}{(k!)^2} = J_0(ix),$$

where  $J_0$  is the Bessel function of the first kind of order 0.

#### Parameters

**x** [array\_like] Argument (float)

#### Returns

**I** [ndarray] Value of the modified Bessel function of order 0 at  $x$ .

See also:

`iv`, `i0e`

## Notes

The range is partitioned into the two intervals  $[0, 8]$  and  $(8, \infty)$ . Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine `i0`.

## References

[1]

### scipy.special.i0e

`scipy.special.i0e(x) = <ufunc 'i0e'>`  
Exponentially scaled modified Bessel function of order 0.

Defined as:

$$i0e(x) = \exp(-\text{abs}(x)) * i0(x).$$

**Parameters**

**x** [array\_like] Argument (float)

**Returns**

**I** [ndarray] Value of the exponentially scaled modified Bessel function of order 0 at  $x$ .

**See also:**

*iv*, *i0*

**Notes**

The range is partitioned into the two intervals  $[0, 8]$  and  $(8, \text{infinity})$ . Chebyshev polynomial expansions are employed in each interval. The polynomial expansions used are the same as those in *i0*, but they are not multiplied by the dominant exponential factor.

This function is a wrapper for the Cephys [1] routine *i0e*.

**References**

[1]

**scipy.special.i1**

`scipy.special.i1(x) = <ufunc 'i1'>`

Modified Bessel function of order 1.

Defined as,

$$I_1(x) = \frac{1}{2}x \sum_{k=0}^{\infty} \frac{(x^2/4)^k}{k!(k+1)!} = -\iota J_1(\iota x),$$

where  $J_1$  is the Bessel function of the first kind of order 1.

**Parameters**

**x** [array\_like] Argument (float)

**Returns**

**I** [ndarray] Value of the modified Bessel function of order 1 at  $x$ .

**See also:**

*iv*, *i1e*

**Notes**

The range is partitioned into the two intervals  $[0, 8]$  and  $(8, \text{infinity})$ . Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephys [1] routine *i1*.

## References

[1]

### scipy.special.i1e

`scipy.special.i1e(x) = <ufunc 'i1e'>`

Exponentially scaled modified Bessel function of order 1.

Defined as:

$$i1e(x) = \exp(-\text{abs}(x)) * i1(x)$$

#### Parameters

**x** [array\_like] Argument (float)

#### Returns

**I** [ndarray] Value of the exponentially scaled modified Bessel function of order 1 at  $x$ .

See also:

*iv, i1*

## Notes

The range is partitioned into the two intervals  $[0, 8]$  and  $(8, \text{infinity})$ . Chebyshev polynomial expansions are employed in each interval. The polynomial expansions used are the same as those in *i1*, but they are not multiplied by the dominant exponential factor.

This function is a wrapper for the Cephes [1] routine *i1e*.

## References

[1]

### scipy.special.k0

`scipy.special.k0(x) = <ufunc 'k0'>`

Modified Bessel function of the second kind of order 0,  $K_0$ .

This function is also sometimes referred to as the modified Bessel function of the third kind of order 0.

#### Parameters

**x** [array\_like] Argument (float).

#### Returns

**K** [ndarray] Value of the modified Bessel function  $K_0$  at  $x$ .

See also:

*kv, k0e*

## Notes

The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine *k0*.

## References

[1]

### scipy.special.k0e

`scipy.special.k0e(x) = <ufunc 'k0e'>`  
 Exponentially scaled modified Bessel function K of order 0

Defined as:

$$k0e(x) = \exp(x) * k0(x) .$$

#### Parameters

**x** [array\_like] Argument (float)

#### Returns

**K** [ndarray] Value of the exponentially scaled modified Bessel function K of order 0 at *x*.

#### See also:

*kv*, *k0*

## Notes

The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephes [1] routine *k0e*.

## References

[1]

### scipy.special.k1

`scipy.special.k1(x) = <ufunc 'k1'>`  
 Modified Bessel function of the second kind of order 1,  $K_1(x)$ .

#### Parameters

**x** [array\_like] Argument (float)

#### Returns

**K** [ndarray] Value of the modified Bessel function K of order 1 at *x*.

**See also:***kv, k1e***Notes**

The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephys [1] routine *k1*.

**References**

[1]

**scipy.special.k1e**

`scipy.special.k1e(x) = <ufunc 'k1e'>`

Exponentially scaled modified Bessel function K of order 1

Defined as:

$$k1e(x) = \exp(x) * k1(x)$$

**Parameters**

**x** [array\_like] Argument (float)

**Returns**

**K** [ndarray] Value of the exponentially scaled modified Bessel function K of order 1 at x.

**See also:***kv, k1***Notes**

The range is partitioned into the two intervals [0, 2] and (2, infinity). Chebyshev polynomial expansions are employed in each interval.

This function is a wrapper for the Cephys [1] routine *k1e*.

**Integrals of Bessel Functions**

<code>itj0y0(x)</code>	Integrals of Bessel functions of order 0
<code>it2j0y0(x)</code>	Integrals related to Bessel functions of order 0
<code>iti0k0(x)</code>	Integrals of modified Bessel functions of order 0
<code>it2i0k0(x)</code>	Integrals related to modified Bessel functions of order 0
<code>besselpoly(a, lmb, nu)</code>	Weighted integral of a Bessel function.

**scipy.special.itj0y0**

`scipy.special.itj0y0(x) = <ufunc 'itj0y0'>`

Integrals of Bessel functions of order 0

Returns simple integrals from 0 to  $x$  of the zeroth order Bessel functions  $j_0$  and  $y_0$ .

**Returns**

**ij0, iy0**

**scipy.special.it2j0y0**

`scipy.special.it2j0y0(x) = <ufunc 'it2j0y0'>`

Integrals related to Bessel functions of order 0

**Returns**

**ij0**      `integral((1-j0(t))/t, t=0..x)`  
**iy0**      `integral(y0(t)/t, t=x..inf)`

**scipy.special.iti0k0**

`scipy.special.iti0k0(x) = <ufunc 'iti0k0'>`

Integrals of modified Bessel functions of order 0

Returns simple integrals from 0 to  $x$  of the zeroth order modified Bessel functions  $i_0$  and  $k_0$ .

**Returns**

**ii0, ik0**

**scipy.special.it2i0k0**

`scipy.special.it2i0k0(x) = <ufunc 'it2i0k0'>`

Integrals related to modified Bessel functions of order 0

**Returns**

**ii0**      `integral((i0(t)-1)/t, t=0..x)`  
**ik0**      `integral(k0(t)/t, t=x..inf)`

**scipy.special.besselpoly**

`scipy.special.besselpoly(a, lmb, nu)` = <ufunc 'besselpoly'>  
 Weighted integral of a Bessel function.

$$\int_0^1 x^\lambda J_\nu(2ax) dx$$

where  $J_\nu$  is a Bessel function and  $\lambda = lmb, \nu = nu$ .

**Derivatives of Bessel Functions**

<code>jvp(v, z[, n])</code>	Compute nth derivative of Bessel function $J_\nu(z)$ with respect to $z$ .
<code>yvp(v, z[, n])</code>	Compute nth derivative of Bessel function $Y_\nu(z)$ with respect to $z$ .
<code>kvp(v, z[, n])</code>	Compute nth derivative of real-order modified Bessel function $K_\nu(z)$
<code>ivp(v, z[, n])</code>	Compute nth derivative of modified Bessel function $I_\nu(z)$ with respect to $z$ .
<code>h1vp(v, z[, n])</code>	Compute nth derivative of Hankel function $H_{1\nu}(z)$ with respect to $z$ .
<code>h2vp(v, z[, n])</code>	Compute nth derivative of Hankel function $H_{2\nu}(z)$ with respect to $z$ .

**scipy.special.jvp**

`scipy.special.jvp(v, z, n=1)`  
 Compute nth derivative of Bessel function  $J_\nu(z)$  with respect to  $z$ .

**Parameters**

**v** [float] Order of Bessel function  
**z** [complex] Argument at which to evaluate the derivative  
**n** [int, default 1] Order of derivative

**Notes**

The derivative is computed using the relation DLFM 10.6.7 [2].

**References**

[1], [2]

**scipy.special.yvp**

`scipy.special.yvp(v, z, n=1)`  
 Compute nth derivative of Bessel function  $Y_\nu(z)$  with respect to  $z$ .

**Parameters**

**v** [float] Order of Bessel function

**z** [complex] Argument at which to evaluate the derivative  
**n** [int, default 1] Order of derivative

### Notes

The derivative is computed using the relation DLFM 10.6.7 [2].

[1], [2]

## scipy.special.kvp

`scipy.special.kvp(v, z, n=1)`

Compute nth derivative of real-order modified Bessel function  $K_v(z)$

$K_v(z)$  is the modified Bessel function of the second kind. Derivative is calculated with respect to  $z$ .

#### Parameters

**v** [array\_like of float] Order of Bessel function  
**z** [array\_like of complex] Argument at which to evaluate the derivative  
**n** [int] Order of derivative. Default is first derivative.

#### Returns

**out** [ndarray] The results

### Notes

The derivative is computed using the relation DLFM 10.29.5 [2].

### References

[1], [2]

### Examples

Calculate multiple values at order 5:

```
>>> from scipy.special import kvp
>>> kvp(5, (1, 2, 3+5j))
array([-1.84903536e+03+0.j, -2.57735387e+01+0.j,
 -3.06627741e-02+0.08750845j])
```

Calculate for a single value at multiple orders:

```
>>> kvp((4, 4.5, 5), 1)
array([-184.0309, -568.9585, -1849.0354])
```

**scipy.special.ivp**`scipy.special.ivp(v, z, n=1)`Compute nth derivative of modified Bessel function  $I_\nu(z)$  with respect to  $z$ .*Parameters*

<b>v</b>	[array_like of float] Order of Bessel function
<b>z</b>	[array_like of complex] Argument at which to evaluate the derivative
<b>n</b>	[int, default 1] Order of derivative

**Notes**

The derivative is computed using the relation DLFM 10.29.5 [2].

## Spherical Bessel Functions

<code>spherical_jn(n, z[, derivative])</code>	Spherical Bessel function of the first kind or its derivative.
<code>spherical_yn(n, z[, derivative])</code>	Spherical Bessel function of the second kind or its derivative.
<code>spherical_in(n, z[, derivative])</code>	Modified spherical Bessel function of the first kind or its derivative.
<code>spherical_kn(n, z[, derivative])</code>	Modified spherical Bessel function of the second kind or its derivative.

### scipy.special.spherical\_jn

`scipy.special.spherical_jn(n, z, derivative=False)`  
 Spherical Bessel function of the first kind or its derivative.

Defined as [1],

$$j_n(z) = \sqrt{\frac{\pi}{2z}} J_{n+1/2}(z),$$

where  $J_n$  is the Bessel function of the first kind.

#### Parameters

- n** [int, array\_like] Order of the Bessel function ( $n \geq 0$ ).
- z** [complex or float, array\_like] Argument of the Bessel function.
- derivative** [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

#### Returns

- jn** [ndarray]

## Notes

For real arguments greater than the order, the function is computed using the ascending recurrence [2]. For small real or complex arguments, the definitional relation to the cylindrical Bessel function of the first kind is used.

The derivative is computed using the relations [3],

$$j'_n(z) = j_{n-1}(z) - \frac{n+1}{z} j_n(z).$$

$$j'_0(z) = -j_1(z)$$

New in version 0.18.0.

## References

[1], [2], [3]

**scipy.special.spherical\_yn**`scipy.special.spherical_yn` (*n*, *z*, *derivative=False*)

Spherical Bessel function of the second kind or its derivative.

Defined as [1],

$$y_n(z) = \sqrt{\frac{\pi}{2z}} Y_{n+1/2}(z),$$

where  $Y_n$  is the Bessel function of the second kind.**Parameters**

- n** [int, array\_like] Order of the Bessel function ( $n \geq 0$ ).
- z** [complex or float, array\_like] Argument of the Bessel function.
- derivative** [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

**Returns**

- yn** [ndarray]

**Notes**

For real arguments, the function is computed using the ascending recurrence [2]. For complex arguments, the definitional relation to the cylindrical Bessel function of the second kind is used.

The derivative is computed using the relations [3],

$$y'_n = y_{n-1} - \frac{n+1}{z} y_n.$$

$$y'_0 = -y_1$$

New in version 0.18.0.

**References**

[1], [2], [3]

**scipy.special.spherical\_in**`scipy.special.spherical_in` (*n*, *z*, *derivative=False*)

Modified spherical Bessel function of the first kind or its derivative.

Defined as [1],

$$i_n(z) = \sqrt{\frac{\pi}{2z}} I_{n+1/2}(z),$$

where  $I_n$  is the modified Bessel function of the first kind.**Parameters**

- n** [int, array\_like] Order of the Bessel function ( $n \geq 0$ ).
- z** [complex or float, array\_like] Argument of the Bessel function.
- derivative** [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

**Returns**

- in** [ndarray]

## Notes

The function is computed using its definitional relation to the modified cylindrical Bessel function of the first kind.

The derivative is computed using the relations [2],

$$i'_n = i_{n-1} - \frac{n+1}{z}i_n.$$
$$i'_1 = i_0$$

New in version 0.18.0.

## References

[1], [2]

## scipy.special.spherical\_kn

`scipy.special.spherical_kn` (*n*, *z*, *derivative=False*)

Modified spherical Bessel function of the second kind or its derivative.

Defined as [1],

$$k_n(z) = \sqrt{\frac{\pi}{2z}} K_{n+1/2}(z),$$

where  $K_n$  is the modified Bessel function of the second kind.

### Parameters

- n** [int, array\_like] Order of the Bessel function ( $n \geq 0$ ).
- z** [complex or float, array\_like] Argument of the Bessel function.
- derivative** [bool, optional] If True, the value of the derivative (rather than the function itself) is returned.

### Returns

- kn** [ndarray]

## Notes

The function is computed using its definitional relation to the modified cylindrical Bessel function of the second kind.

The derivative is computed using the relations [2],

$$k'_n = -k_{n-1} - \frac{n+1}{z}k_n.$$
$$k'_0 = -k_1$$

New in version 0.18.0.

## References

## Riccati-Bessel Functions

These are not universal functions:

<code>riccati_jn(n, x)</code>	Compute Riccati-Bessel function of the first kind and its derivative.
<code>riccati_yn(n, x)</code>	Compute Riccati-Bessel function of the second kind and its derivative.

### scipy.special.riccati\_jn

`scipy.special.riccati_jn(n, x)`

Compute Riccati-Bessel function of the first kind and its derivative.

The Riccati-Bessel function of the first kind is defined as  $xj_n(x)$ , where  $j_n$  is the spherical Bessel function of the first kind of order  $n$ .

This function computes the value and first derivative of the Riccati-Bessel function for all orders up to and including  $n$ .

#### Parameters

**n** [int] Maximum order of function to compute  
**x** [float] Argument at which to evaluate

#### Returns

**jn** [ndarray] Value of  $j_0(x), \dots, j_n(x)$   
**jnp** [ndarray] First derivative  $j_0'(x), \dots, j_n'(x)$

#### Notes

The computation is carried out via backward recurrence, using the relation DLMF 10.51.1 [2].

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

#### References

[1], [2]

### scipy.special.riccati\_yn

`scipy.special.riccati_yn(n, x)`

Compute Riccati-Bessel function of the second kind and its derivative.

The Riccati-Bessel function of the second kind is defined as  $xy_n(x)$ , where  $y_n$  is the spherical Bessel function of the second kind of order  $n$ .

This function computes the value and first derivative of the function for all orders up to and including  $n$ .

#### Parameters

**n** [int] Maximum order of function to compute  
**x** [float] Argument at which to evaluate

#### Returns

**yn** [ndarray] Value of  $y_0(x), \dots, y_n(x)$   
**ynp** [ndarray] First derivative  $y_0'(x), \dots, y_n'(x)$

### Notes

The computation is carried out via ascending recurrence, using the relation DLMF 10.51.1 [2].

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

### References

[1], [2]

### Struve Functions

<code>struve(v, x)</code>	Struve function.
<code>modstruve(v, x)</code>	Modified Struve function.
<code>itstruve0(x)</code>	Integral of the Struve function of order 0.
<code>it2struve0(x)</code>	Integral related to the Struve function of order 0.
<code>itmodstruve0(x)</code>	Integral of the modified Struve function of order 0.

### scipy.special.struve

`scipy.special.struve(v, x) = <ufunc 'struve'>`

Struve function.

Return the value of the Struve function of order  $\nu$  at  $x$ . The Struve function is defined as,

$$H_\nu(x) = (z/2)^{\nu+1} \sum_{n=0}^{\infty} \frac{(-1)^n (z/2)^{2n}}{\Gamma(n + \frac{3}{2})\Gamma(n + \nu + \frac{3}{2})},$$

where  $\Gamma$  is the gamma function.

#### Parameters

**v** [array\_like] Order of the Struve function (float).  
**x** [array\_like] Argument of the Struve function (float; must be positive unless  $\nu$  is an integer).

#### Returns

**H** [ndarray] Value of the Struve function of order  $\nu$  at  $x$ .

**See also:**

`modstruve`

### Notes

Three methods discussed in [1] are used to evaluate the Struve function:

- power series
- expansion in Bessel functions (if  $|z| < |v| + 20$ )
- asymptotic large- $z$  expansion (if  $z \geq 0.7v + 12$ )

Rounding errors are estimated based on the largest terms in the sums, and the result associated with the smallest error is returned.

## References

[1]

### scipy.special.modstruve

`scipy.special.modstruve(v, x) = <ufunc 'modstruve'>`

Modified Struve function.

Return the value of the modified Struve function of order  $\nu$  at  $x$ . The modified Struve function is defined as,

$$L_\nu(x) = -i \exp(-\pi\nu/2) H_\nu(x),$$

where  $H_\nu$  is the Struve function.

#### Parameters

- v** [array\_like] Order of the modified Struve function (float).
- x** [array\_like] Argument of the Struve function (float; must be positive unless  $\nu$  is an integer).

#### Returns

- L** [ndarray] Value of the modified Struve function of order  $\nu$  at  $x$ .

#### See also:

[\*struve\*](#)

## Notes

Three methods discussed in [1] are used to evaluate the function:

- power series
- expansion in Bessel functions (if  $|z| < |v| + 20$ )
- asymptotic large- $z$  expansion (if  $z \geq 0.7v + 12$ )

Rounding errors are estimated based on the largest terms in the sums, and the result associated with the smallest error is returned.

## References

[1]

### scipy.special.itstruve0

`scipy.special.itstruve0(x) = <ufunc 'itstruve0'>`

Integral of the Struve function of order 0.

$$I = \int_0^x H_0(t) dt$$

#### Parameters

- x** [array\_like] Upper limit of integration (float).

**Returns**

**I** [ndarray] The integral of  $H_0$  from 0 to  $x$ .

**See also:**

*struve*

**Notes**

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

**References**

[1]

**scipy.special.it2struve0**

`scipy.special.it2struve0(x) = <ufunc 'it2struve0'>`  
 Integral related to the Struve function of order 0.

Returns the integral,

$$\int_x^\infty \frac{H_0(t)}{t} dt$$

where  $H_0$  is the Struve function of order 0.

**Parameters**

**x** [array\_like] Lower limit of integration.

**Returns**

**I** [ndarray] The value of the integral.

**See also:**

*struve*

**Notes**

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

**References**

[1]

**scipy.special.itmodstruve0**

`scipy.special.itmodstruve0(x) = <ufunc 'itmodstruve0'>`  
 Integral of the modified Struve function of order 0.

$$I = \int_0^x L_0(t) dt$$

**Parameters**

**x** [array\_like] Upper limit of integration (float).

**Returns**

**I** [ndarray] The integral of  $L_0$  from 0 to  $x$ .

**Notes**

Wrapper for a Fortran routine created by Shanjie Zhang and Jianming Jin [1].

**References**

<code>stdtr</code> (df, t)	Student $t$ distribution cumulative distribution function
<code>stdtridf</code> (p, t)	Inverse of <code>stdtr</code> vs df
<code>stdtrit</code> (df, p)	Inverse of <code>stdtr</code> vs $t$
<code>chdtr</code> (v, x)	Chi square cumulative distribution function
<code>chdtrc</code> (v, x)	Chi square survival function
<code>chdtri</code> (v, p)	Inverse to <code>chdtrc</code>
<code>chdtriv</code> (p, x)	Inverse to <code>chdtr</code> vs $v$
<code>ndtr</code> (x)	Gaussian cumulative distribution function.
<code>log_ndtr</code> (x)	Logarithm of Gaussian cumulative distribution function.
<code>ndtri</code> (y)	Inverse of <code>ndtr</code> vs $x$
<code>chndtr</code> (x, df, nc)	Non-central chi square cumulative distribution function
<code>chndtridf</code> (x, p, nc)	Inverse to <code>chndtr</code> vs $df$
<code>chndtrinc</code> (x, df, p)	Inverse to <code>chndtr</code> vs $nc$
<code>chndtrix</code> (p, df, nc)	Inverse to <code>chndtr</code> vs $x$
<code>smirnov</code> (n, d)	Kolmogorov-Smirnov complementary cumulative distribution function
<code>smirnovi</code> (n, p)	Inverse to <code>smirnov</code>
<code>kolmogorov</code> (y)	Complementary cumulative distribution (Survival Function) function of Kolmogorov distribution.
<code>kolmogi</code> (p)	Inverse Survival Function of Kolmogorov distribution
<code>tklmbda</code> (x, lmbda)	Tukey-Lambda cumulative distribution function
<code>logit</code> (x)	Logit ufunc for ndarrays.
<code>expit</code> (x)	Expit (a.k.a.
<code>boxcox</code> (x, lmbda)	Compute the Box-Cox transformation.
<code>boxcox1p</code> (x, lmbda)	Compute the Box-Cox transformation of $1 + x$ .
<code>inv_boxcox</code> (y, lmbda)	Compute the inverse of the Box-Cox transformation.
<code>inv_boxcox1p</code> (y, lmbda)	Compute the inverse of the Box-Cox transformation.
<code>owens_t</code> (h, a)	Owen's T Function.

**scipy.special.bdtr**

`scipy.special.bdtr`( $k, n, p$ ) = <ufunc 'bdtr'>  
 Binomial distribution cumulative distribution function.

Sum of the terms 0 through  $k$  of the Binomial probability density.

$$\text{bdtr}(k, n, p) = \sum_{j=0}^k \binom{n}{j} p^j (1-p)^{n-j}$$

#### Parameters

<b>k</b>	[array_like] Number of successes (int).
<b>n</b>	[array_like] Number of events (int).
<b>p</b>	[array_like] Probability of success in a single event (float).

#### Returns

<b>y</b>	[ndarray] Probability of $k$ or fewer successes in $n$ independent events with success probabilities of $p$ .
----------	---------------------------------------------------------------------------------------------------------------

#### Notes

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\text{bdtr}(k, n, p) = I_{1-p}(n-k, k+1).$$

Wrapper for the Cephys [1] routine `bdtr`.

#### References

[1]

#### `scipy.special.bdtrc`

`scipy.special.bdtrc(k, n, p) = <ufunc 'bdtrc'>`  
Binomial distribution survival function.

Sum of the terms  $k + 1$  through  $n$  of the binomial probability density,

$$\text{bdtrc}(k, n, p) = \sum_{j=k+1}^n \binom{n}{j} p^j (1-p)^{n-j}$$

#### Parameters

<b>k</b>	[array_like] Number of successes (int).
<b>n</b>	[array_like] Number of events (int)
<b>p</b>	[array_like] Probability of success in a single event.

#### Returns

<b>y</b>	[ndarray] Probability of $k + 1$ or more successes in $n$ independent events with success probabilities of $p$ .
----------	------------------------------------------------------------------------------------------------------------------

See also:

`bdtr`, `betainc`

## Notes

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\text{bdtrc}(k, n, p) = I_p(k + 1, n - k).$$

Wrapper for the Cephes [1] routine `bdtrc`.

## References

[1]

### scipy.special.bdtri

`scipy.special.bdtri(k, n, y) = <ufunc 'bdtri'>`

Inverse function to `bdtr` with respect to  $p$ .

Finds the event probability  $p$  such that the sum of the terms 0 through  $k$  of the binomial probability density is equal to the given cumulative probability  $y$ .

#### Parameters

**k** [array\_like] Number of successes (float).  
**n** [array\_like] Number of events (float).  
**y** [array\_like] Cumulative probability (probability of  $k$  or fewer successes in  $n$  events).

#### Returns

**p** [ndarray] The event probability such that  $\text{bdtr}(k, n, p) = y$ .

#### See also:

`bdtr`, `betaincinv`

## Notes

The computation is carried out using the inverse beta integral function and the relation,:

$$1 - p = \text{betaincinv}(n - k, k + 1, y).$$

Wrapper for the Cephes [1] routine `bdtri`.

## References

[1]

### scipy.special.bdtrik

`scipy.special.bdtrik(y, n, p) = <ufunc 'bdtrik'>`

Inverse function to `bdtr` with respect to  $k$ .

Finds the number of successes  $k$  such that the sum of the terms 0 through  $k$  of the Binomial probability density for  $n$  events with probability  $p$  is equal to the given cumulative probability  $y$ .

#### Parameters

**y** [array\_like] Cumulative probability (probability of  $k$  or fewer successes in  $n$  events).

**n** [array\_like] Number of events (float).  
**p** [array\_like] Success probability (float).

**Returns**

**k** [ndarray] The number of successes  $k$  such that  $bdtr(k, n, p) = y$ .

**See also:**

*bdtr*

**Notes**

Formula 26.5.24 of [1] is used to reduce the binomial distribution to the cumulative incomplete beta distribution.

Computation of  $k$  involves a search for a value that produces the desired value of  $y$ . The search relies on the monotonicity of  $y$  with  $k$ .

Wrapper for the CDFLIB [2] Fortran routine *cdfbin*.

**References**

[1], [2]

**scipy.special.bdtrin**

`scipy.special.bdtrin(k, y, p) = <ufunc 'bdtrin'>`

Inverse function to *bdtr* with respect to  $n$ .

Finds the number of events  $n$  such that the sum of the terms 0 through  $k$  of the Binomial probability density for events with probability  $p$  is equal to the given cumulative probability  $y$ .

**Parameters**

**k** [array\_like] Number of successes (float).  
**y** [array\_like] Cumulative probability (probability of  $k$  or fewer successes in  $n$  events).  
**p** [array\_like] Success probability (float).

**Returns**

**n** [ndarray] The number of events  $n$  such that  $bdtr(k, n, p) = y$ .

**See also:**

*bdtr*

**Notes**

Formula 26.5.24 of [1] is used to reduce the binomial distribution to the cumulative incomplete beta distribution.

Computation of  $n$  involves a search for a value that produces the desired value of  $y$ . The search relies on the monotonicity of  $y$  with  $n$ .

Wrapper for the CDFLIB [2] Fortran routine *cdfbin*.

**References**

[1], [2]

**scipy.special.btdtr**`scipy.special.btdtr(a, b, x) = <ufunc 'btdtr'>`

Cumulative distribution function of the beta distribution.

Returns the integral from zero to  $x$  of the beta probability density function,

$$I = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1-t)^{b-1} dt$$

where  $\Gamma$  is the gamma function.**Parameters**

- a** [array\_like] Shape parameter ( $a > 0$ ).
- b** [array\_like] Shape parameter ( $b > 0$ ).
- x** [array\_like] Upper limit of integration, in  $[0, 1]$ .

**Returns**

- I** [ndarray] Cumulative distribution function of the beta distribution with parameters  $a$  and  $b$  at  $x$ .

**See also:**[\*betainc\*](#)**Notes**This function is identical to the incomplete beta integral function [\*betainc\*](#).Wrapper for the Cephes [1] routine [\*btdtr\*](#).**References**

[1]

**scipy.special.btdtri**`scipy.special.btdtri(a, b, p) = <ufunc 'btdtri'>`The  $p$ -th quantile of the beta distribution.This function is the inverse of the beta cumulative distribution function, [\*btdtr\*](#), returning the value of  $x$  for which  $btdtr(a, b, x) = p$ , or

$$p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1-t)^{b-1} dt$$

**Parameters**

- a** [array\_like] Shape parameter ( $a > 0$ ).
- b** [array\_like] Shape parameter ( $b > 0$ ).
- p** [array\_like] Cumulative probability, in  $[0, 1]$ .

**Returns**

- x** [ndarray] The quantile corresponding to  $p$ .

**See also:**[\*betaincinv\*](#), [\*btdtr\*](#)

## Notes

The value of  $x$  is found by interval halving or Newton iterations.

Wrapper for the Cephes [1] routine *incbi*, which solves the equivalent problem of finding the inverse of the incomplete beta integral.

## References

[1]

### scipy.special.btdtria

`scipy.special.btdtria(p, b, x) = <ufunc 'btdtria'>`  
Inverse of `btdtr` with respect to  $a$ .

This is the inverse of the beta cumulative distribution function, `btdtr`, considered as a function of  $a$ , returning the value of  $a$  for which  $btdtr(a, b, x) = p$ , or

$$p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1-t)^{b-1} dt$$

#### Parameters

- p** [array\_like] Cumulative probability, in [0, 1].
- b** [array\_like] Shape parameter ( $b > 0$ ).
- x** [array\_like] The quantile, in [0, 1].

#### Returns

- a** [ndarray] The value of the shape parameter  $a$  such that  $btdtr(a, b, x) = p$ .

See also:

#### `btdtr`

Cumulative distribution function of the beta distribution.

#### `btdtri`

Inverse with respect to  $x$ .

#### `btdtrib`

Inverse with respect to  $b$ .

## Notes

Wrapper for the CDFLIB [1] Fortran routine *cdfbet*.

The cumulative distribution function  $p$  is computed using a routine by DiDinato and Morris [2]. Computation of  $a$  involves a search for a value that produces the desired value of  $p$ . The search relies on the monotonicity of  $p$  with  $a$ .

## References

**scipy.special.btdtrib**`scipy.special.btdtrib(a, p, x) = <ufunc 'btdtrib'>`Inverse of `btdtr` with respect to  $b$ .

This is the inverse of the beta cumulative distribution function, `btdtr`, considered as a function of  $b$ , returning the value of  $b$  for which  $btdtr(a, b, x) = p$ , or

$$p = \int_0^x \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} t^{a-1} (1-t)^{b-1} dt$$

**Parameters**

- a** [array\_like] Shape parameter ( $a > 0$ ).
- p** [array\_like] Cumulative probability, in  $[0, 1]$ .
- x** [array\_like] The quantile, in  $[0, 1]$ .

**Returns**

- b** [ndarray] The value of the shape parameter  $b$  such that  $btdtr(a, b, x) = p$ .

**See also:****btdtr**

Cumulative distribution function of the beta distribution.

**btdtri**Inverse with respect to  $x$ .**btdtria**Inverse with respect to  $a$ .**Notes**Wrapper for the CDFLIB [1] Fortran routine `cdfbet`.

The cumulative distribution function  $p$  is computed using a routine by DiDinato and Morris [2]. Computation of  $b$  involves a search for a value that produces the desired value of  $p$ . The search relies on the monotonicity of  $p$  with  $b$ .

**References**

[1], [2]

**scipy.special.fdttr**`scipy.special.fdttr(dfn, dfd, x) = <ufunc 'fdttr'>`

F cumulative distribution function.

Returns the value of the cumulative distribution function of the F-distribution, also known as Snedecor's F-distribution or the Fisher-Snedecor distribution.

The F-distribution with parameters  $d_n$  and  $d_d$  is the distribution of the random variable,

$$X = \frac{U_n/d_n}{U_d/d_d},$$

where  $U_n$  and  $U_d$  are random variables distributed  $\chi^2$ , with  $d_n$  and  $d_d$  degrees of freedom, respectively.

**Parameters**

<b>dfn</b>	[array_like] First parameter (positive float).
<b>dfd</b>	[array_like] Second parameter (positive float).
<b>x</b>	[array_like] Argument (nonnegative float).

**Returns**

<b>y</b>	[ndarray] The CDF of the F-distribution with parameters <i>dfn</i> and <i>dfd</i> at <i>x</i> .
----------	-------------------------------------------------------------------------------------------------

**Notes**

The regularized incomplete beta function is used, according to the formula,

$$F(d_n, d_d; x) = I_{x d_n / (d_d + x d_n)}(d_n/2, d_d/2).$$

Wrapper for the Cephes [1] routine *fdtr*.

**References**

[1]

**scipy.special.fdtc**

`scipy.special.fdtc(dfn, dfd, x) = <ufunc 'fdtrc'>`  
F survival function.

Returns the complemented F-distribution function (the integral of the density from *x* to infinity).

**Parameters**

<b>dfn</b>	[array_like] First parameter (positive float).
<b>dfd</b>	[array_like] Second parameter (positive float).
<b>x</b>	[array_like] Argument (nonnegative float).

**Returns**

<b>y</b>	[ndarray] The complemented F-distribution function with parameters <i>dfn</i> and <i>dfd</i> at <i>x</i> .
----------	------------------------------------------------------------------------------------------------------------

**See also:**

*fdtr*

**Notes**

The regularized incomplete beta function is used, according to the formula,

$$F(d_n, d_d; x) = I_{d_d / (d_d + x d_n)}(d_d/2, d_n/2).$$

Wrapper for the Cephes [1] routine *fdtrc*.

**References**

[1]

### scipy.special.fdtri

`scipy.special.fdtri(dfn, dfd, p) = <ufunc 'fdtri'>`

The  $p$ -th quantile of the F-distribution.

This function is the inverse of the F-distribution CDF, `fdtr`, returning the  $x$  such that  $fdtr(dfn, dfd, x) = p$ .

#### Parameters

**dfn** [array\_like] First parameter (positive float).  
**dfd** [array\_like] Second parameter (positive float).  
**p** [array\_like] Cumulative probability, in [0, 1].

#### Returns

**x** [ndarray] The quantile corresponding to  $p$ .

### Notes

The computation is carried out using the relation to the inverse regularized beta function,  $I_x^{-1}(a, b)$ . Let  $z = I_p^{-1}(d_d/2, d_n/2)$ . Then,

$$x = \frac{d_d(1-z)}{d_n z}.$$

If  $p$  is such that  $x < 0.5$ , the following relation is used instead for improved stability: let  $z' = I_{1-p}^{-1}(d_n/2, d_d/2)$ . Then,

$$x = \frac{d_d z'}{d_n(1-z')}.$$

Wrapper for the Cephes [1] routine `fdtri`.

### References

[1]

### scipy.special.fdtridfd

`scipy.special.fdtridfd(dfn, p, x) = <ufunc 'fdtridfd'>`

Inverse to `fdtr` vs `dfd`

Finds the F density argument `dfd` such that `fdtr(dfn, dfd, x) == p`.

### scipy.special.gdtr

`scipy.special.gdtr(a, b, x) = <ufunc 'gdtr'>`

Gamma distribution cumulative distribution function.

Returns the integral from zero to  $x$  of the gamma probability density function,

$$F = \int_0^x \frac{a^b}{\Gamma(b)} t^{b-1} e^{-at} dt,$$

where  $\Gamma$  is the gamma function.

#### Parameters

**a** [array\_like] The rate parameter of the gamma distribution, sometimes denoted  $\beta$  (float). It is also the reciprocal of the scale parameter  $\theta$ .

**b** [array\_like] The shape parameter of the gamma distribution, sometimes denoted  $\alpha$  (float).  
**x** [array\_like] The quantile (upper limit of integration; float).

**Returns**

**F** [ndarray] The CDF of the gamma distribution with parameters  $a$  and  $b$  evaluated at  $x$ .

**See also:****gdtrc**

1 - CDF of the gamma distribution.

**Notes**

The evaluation is carried out using the relation to the incomplete gamma integral (regularized gamma function).

Wrapper for the Cephes [1] routine *gdtcr*.

**References**

[1]

**scipy.special.gdtrc**

`scipy.special.gdtrc(a, b, x) = <ufunc 'gdtrc'>`

Gamma distribution survival function.

Integral from  $x$  to infinity of the gamma probability density function,

$$F = \int_x^{\infty} \frac{a^b}{\Gamma(b)} t^{b-1} e^{-at} dt,$$

where  $\Gamma$  is the gamma function.

**Parameters**

**a** [array\_like] The rate parameter of the gamma distribution, sometimes denoted  $\beta$  (float). It is also the reciprocal of the scale parameter  $\theta$ .  
**b** [array\_like] The shape parameter of the gamma distribution, sometimes denoted  $\alpha$  (float).  
**x** [array\_like] The quantile (lower limit of integration; float).

**Returns**

**F** [ndarray] The survival function of the gamma distribution with parameters  $a$  and  $b$  evaluated at  $x$ .

**See also:**

*gdtcr*, *gdtcrx*

**Notes**

The evaluation is carried out using the relation to the incomplete gamma integral (regularized gamma function).

Wrapper for the Cephes [1] routine *gdtcr*.

### scipy.special.gdtria

`scipy.special.gdtria(p, b, x, out=None) = <ufunc 'gdtria'>`

Inverse of `gdr` vs  $a$ .

Returns the inverse with respect to the parameter  $a$  of  $p = \text{gdr}(a, b, x)$ , the cumulative distribution function of the gamma distribution.

#### Parameters

<b>p</b>	[array_like] Probability values.
<b>b</b>	[array_like] $b$ parameter values of $\text{gdr}(a, b, x)$ . $b$ is the “shape” parameter of the gamma distribution.
<b>x</b>	[array_like] Nonnegative real values, from the domain of the gamma distribution.
<b>out</b>	[ndarray, optional] If a fourth argument is given, it must be a <code>numpy.ndarray</code> whose size matches the broadcast result of $a$ , $b$ and $x$ . <i>out</i> is then the array returned by the function.

#### Returns

<b>a</b>	[ndarray] Values of the $a$ parameter such that $p = \text{gdr}(a, b, x)$ . $1/a$ is the “scale” parameter of the gamma distribution.
----------	---------------------------------------------------------------------------------------------------------------------------------------

See also:

#### `gdr`

CDF of the gamma distribution.

#### `gdrrib`

Inverse with respect to  $b$  of  $\text{gdr}(a, b, x)$ .

#### `gdrrix`

Inverse with respect to  $x$  of  $\text{gdr}(a, b, x)$ .

## Notes

Wrapper for the CDFLIB [1] Fortran routine `cdfgam`.

The cumulative distribution function  $p$  is computed using a routine by DiDinato and Morris [2]. Computation of  $a$  involves a search for a value that produces the desired value of  $p$ . The search relies on the monotonicity of  $p$  with  $a$ .

## References

[1], [2]

## Examples

First evaluate `gdr`.

```
>>> from scipy.special import gdtr, gdtria
>>> p = gdtr(1.2, 3.4, 5.6)
>>> print(p)
0.94378087442
```

Verify the inverse.

```
>>> gdtria(p, 3.4, 5.6)
1.2
```

### scipy.special.gdtrib

`scipy.special.gdtrib(a, p, x, out=None) = <ufunc 'gdtrib'>`

Inverse of `gdtr` vs `b`.

Returns the inverse with respect to the parameter  $b$  of  $p = \text{gdtr}(a, b, x)$ , the cumulative distribution function of the gamma distribution.

#### Parameters

- a** [array\_like]  $a$  parameter values of  $\text{gdtr}(a, b, x)$ .  $1/a$  is the “scale” parameter of the gamma distribution.
- p** [array\_like] Probability values.
- x** [array\_like] Nonnegative real values, from the domain of the gamma distribution.
- out** [ndarray, optional] If a fourth argument is given, it must be a `numpy.ndarray` whose size matches the broadcast result of  $a$ ,  $b$  and  $x$ . `out` is then the array returned by the function.

#### Returns

- b** [ndarray] Values of the  $b$  parameter such that  $p = \text{gdtr}(a, b, x)$ .  $b$  is the “shape” parameter of the gamma distribution.

See also:

#### `gdtr`

CDF of the gamma distribution.

#### `gdtria`

Inverse with respect to  $a$  of  $\text{gdtr}(a, b, x)$ .

#### `gdtrix`

Inverse with respect to  $x$  of  $\text{gdtr}(a, b, x)$ .

### Notes

Wrapper for the CDFLIB [1] Fortran routine `cdfgam`.

The cumulative distribution function  $p$  is computed using a routine by DiDinato and Morris [2]. Computation of  $b$  involves a search for a value that produces the desired value of  $p$ . The search relies on the monotonicity of  $p$  with  $b$ .

## scipy.special.gdftrib

`scipy.special.gdftrib(a, b, p, out=None) = <ufunc 'gdftrib'>`

Inverse of `gdftr` vs  $x$ .

Returns the inverse with respect to the parameter  $x$  of  $p = gdftr(a, b, x)$ , the cumulative distribution function of the gamma distribution. This is also known as the  $p$ 'th quantile of the distribution.

### Parameters

- a** [array\_like]  $a$  parameter values of  $gdftr(a, b, x)$ .  $1/a$  is the “scale” parameter of the gamma distribution.
- b** [array\_like]  $b$  parameter values of  $gdftr(a, b, x)$ .  $b$  is the “shape” parameter of the gamma distribution.
- p** [array\_like] Probability values.
- out** [ndarray, optional] If a fourth argument is given, it must be a `numpy.ndarray` whose size matches the broadcast result of  $a$ ,  $b$  and  $x$ . `out` is then the array returned by the function.

### Returns

- x** [ndarray] Values of the  $x$  parameter such that  $p = gdftr(a, b, x)$ .

**See also:**

### `gdftr`

CDF of the gamma distribution.

### `gdftria`

Inverse with respect to  $a$  of  $gdftr(a, b, x)$ .

### `gdftrib`

Inverse with respect to  $b$  of  $gdftr(a, b, x)$ .

## Notes

Wrapper for the CDFLIB [1] Fortran routine `cdfgam`.

The cumulative distribution function  $p$  is computed using a routine by DiDinato and Morris [2]. Computation of  $x$  involves a search for a value that produces the desired value of  $p$ . The search relies on the monotonicity of  $p$  with  $x$ .

5.5999999999999996
```

## scipy.special.nbdtr

`scipy.special.nbdtr(k, n, p) = <ufunc 'nbdtr'>`

Negative binomial cumulative distribution function.

Returns the sum of the terms 0 through  $k$  of the negative binomial distribution probability mass function,

$$F = \sum_{j=0}^k \binom{n+j-1}{j} p^n (1-p)^j.$$

In a sequence of Bernoulli trials with individual success probabilities  $p$ , this is the probability that  $k$  or fewer failures precede the  $n$ th success.

### Parameters

**k** [array\_like] The maximum number of allowed failures (nonnegative int).  
**n** [array\_like] The target number of successes (positive int).  
**p** [array\_like] Probability of success in a single event (float).

### Returns

**F** [ndarray] The probability of  $k$  or fewer failures before  $n$  successes in a sequence of events with individual success probability  $p$ .

### See also:

`nbdtrc`

## Notes

If floating point values are passed for  $k$  or  $n$ , they will be truncated to integers.

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\text{nbdtr}(k, n, p) = I_p(n, k + 1).$$

Wrapper for the Cephes [1] routine `nbdtr`.

## References

[1]

### scipy.special.nbdtrc

`scipy.special.nbdtrc(k, n, p) = <ufunc 'nbdtrc'>`

Negative binomial survival function.

Returns the sum of the terms  $k + 1$  to infinity of the negative binomial distribution probability mass function,

$$F = \sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j.$$

In a sequence of Bernoulli trials with individual success probabilities  $p$ , this is the probability that more than  $k$  failures precede the  $n$ th success.

#### Parameters

- k** [array\_like] The maximum number of allowed failures (nonnegative int).
- n** [array\_like] The target number of successes (positive int).
- p** [array\_like] Probability of success in a single event (float).

#### Returns

- F** [ndarray] The probability of  $k + 1$  or more failures before  $n$  successes in a sequence of events with individual success probability  $p$ .

## Notes

If floating point values are passed for  $k$  or  $n$ , they will be truncated to integers.

The terms are not summed directly; instead the regularized incomplete beta function is employed, according to the formula,

$$\text{nbdtrc}(k, n, p) = I_{1-p}(k + 1, n).$$

Wrapper for the Cephes [1] routine `nbdtrc`.

## References

[1]

### scipy.special.nbdtri

`scipy.special.nbdtri(k, n, y) = <ufunc 'nbdtri'>`

Inverse of `nbdtr` vs  $p$ .

Returns the inverse with respect to the parameter  $p$  of  $y = \text{nbdtr}(k, n, p)$ , the negative binomial cumulative distribution function.

#### Parameters

- k** [array\_like] The maximum number of allowed failures (nonnegative int).
- n** [array\_like] The target number of successes (positive int).
- y** [array\_like] The probability of  $k$  or fewer failures before  $n$  successes (float).

#### Returns

**p** [ndarray] Probability of success in a single event (float) such that  $nbdr(k, n, p) = y$ .

**See also:**

[nbdr](#)

Cumulative distribution function of the negative binomial.

[nbdrk](#)

Inverse with respect to  $k$  of  $nbdr(k, n, p)$ .

[nbdrin](#)

Inverse with respect to  $n$  of  $nbdr(k, n, p)$ .

## Notes

Wrapper for the Cephes [1] routine `nbdr`.

## References

[1]

### `scipy.special.nbdrk`

`scipy.special.nbdrk(y, n, p) = <ufunc 'nbdrk'>`

Inverse of `nbdr` vs  $k$ .

Returns the inverse with respect to the parameter  $k$  of  $y = nbdr(k, n, p)$ , the negative binomial cumulative distribution function.

#### *Parameters*

**y** [array\_like] The probability of  $k$  or fewer failures before  $n$  successes (float).  
**n** [array\_like] The target number of successes (positive int).  
**p** [array\_like] Probability of success in a single event (float).

#### *Returns*

**k** [ndarray] The maximum number of allowed failures such that  $nbdr(k, n, p) = y$ .

**See also:**

[nbdr](#)

Cumulative distribution function of the negative binomial.

[nbdr](#)

Inverse with respect to  $p$  of  $nbdr(k, n, p)$ .

[nbdrin](#)

Inverse with respect to  $n$  of  $nbdr(k, n, p)$ .

## Notes

Wrapper for the CDFLIB [1] Fortran routine *cdfnbn*.

Formula 26.5.26 of [2],

$$\sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j = I_{1-p}(k+1, n),$$

is used to reduce calculation of the cumulative distribution function to that of a regularized incomplete beta  $I$ .

Computation of  $k$  involves a search for a value that produces the desired value of  $y$ . The search relies on the monotonicity of  $y$  with  $k$ .

## References

[1], [2]

### scipy.special.nbdtrin

`scipy.special.nbdtrin(k, y, p) = <ufunc 'nbdtrin'>`

Inverse of *nbdtr* vs  $n$ .

Returns the inverse with respect to the parameter  $n$  of  $y = nbdtr(k, n, p)$ , the negative binomial cumulative distribution function.

#### Parameters

**k** [array\_like] The maximum number of allowed failures (nonnegative int).  
**y** [array\_like] The probability of  $k$  or fewer failures before  $n$  successes (float).  
**p** [array\_like] Probability of success in a single event (float).

#### Returns

**n** [ndarray] The number of successes  $n$  such that  $nbdtr(k, n, p) = y$ .

See also:

#### *nbdtr*

Cumulative distribution function of the negative binomial.

#### *nbdtri*

Inverse with respect to  $p$  of  $nbdtr(k, n, p)$ .

#### *nbdtrik*

Inverse with respect to  $k$  of  $nbdtr(k, n, p)$ .

## Notes

Wrapper for the CDFLIB [1] Fortran routine *cdfnbn*.

Formula 26.5.26 of [2],

$$\sum_{j=k+1}^{\infty} \binom{n+j-1}{j} p^n (1-p)^j = I_{1-p}(k+1, n),$$

is used to reduce calculation of the cumulative distribution function to that of a regularized incomplete beta  $I$ .

Computation of  $n$  involves a search for a value that produces the desired value of  $y$ . The search relies on the monotonicity of  $y$  with  $n$ .

## scipy.special.ncfdtr

`scipy.special.ncfdtr(dfn, dfd, nc, f) = <ufunc 'ncfdtr'>`

Cumulative distribution function of the non-central F distribution.

The non-central F describes the distribution of,

$$Z = \frac{X/d_n}{Y/d_d}$$

where  $X$  and  $Y$  are independently distributed, with  $X$  distributed non-central  $\chi^2$  with noncentrality parameter  $nc$  and  $d_n$  degrees of freedom, and  $Y$  distributed  $\chi^2$  with  $d_d$  degrees of freedom.

### Parameters

<b>dfn</b>	[array_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).
<b>dfd</b>	[array_like] Degrees of freedom of the denominator sum of squares. Range (0, inf).
<b>nc</b>	[array_like] Noncentrality parameter. Should be in range (0, 1e4).
<b>f</b>	[array_like] Quantiles, i.e. the upper limit of integration.

### Returns

<b>cdf</b>	[float or ndarray] The calculated CDF. If all inputs are scalar, the return will be a float. Otherwise it will be an array.
------------	-----------------------------------------------------------------------------------------------------------------------------

See also:

### ncfdtri

Quantile function; inverse of `ncfdtr` with respect to  $f$ .

### ncfdtridfd

Inverse of `ncfdtr` with respect to  $dfd$ .

### ncfdtridfn

Inverse of `ncfdtr` with respect to  $dfn$ .

### ncfdtrinc

Inverse of `ncfdtr` with respect to  $nc$ .

## Notes

Wrapper for the CDFLIB [1] Fortran routine `cdffnc`.

The cumulative distribution function is computed using Formula 26.6.20 of [2]:

$$F(d_n, d_d, n_c, f) = \sum_{j=0}^{\infty} e^{-n_c/2} \frac{(n_c/2)^j}{j!} I_x\left(\frac{d_n}{2} + j, \frac{d_d}{2}\right),$$

where  $I$  is the regularized incomplete beta function, and  $x = fd_n/(fd_n + d_d)$ .

The computation time required for this routine is proportional to the noncentrality parameter  $nc$ . Very large values of this parameter can consume immense computer resources. This is why the search range is bounded by 10,000.

## References

[1], [2]

## Examples

```
>>> from scipy import special
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

Plot the CDF of the non-central F distribution, for  $nc=0$ . Compare with the F-distribution from `scipy.stats`:

```
>>> x = np.linspace(-1, 8, num=500)
>>> dfn = 3
>>> dfd = 2
>>> ncf_stats = stats.f.cdf(x, dfn, dfd)
>>> ncf_special = special.ncfdtr(dfn, dfd, 0, x)
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, ncf_stats, 'b-', lw=3)
>>> ax.plot(x, ncf_special, 'r-')
>>> plt.show()
```

### `scipy.special.ncfdtridfd`

`scipy.special.ncfdtridfd(dfn, p, nc, f) = <ufunc 'ncfdtridfd'>`

Calculate degrees of freedom (denominator) for the noncentral F-distribution.

This is the inverse with respect to  $dfd$  of `ncfdtr`. See `ncfdtr` for more details.

**Parameters**

<b>dfn</b>	[array_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).
<b>p</b>	[array_like] Value of the cumulative distribution function. Must be in the range [0, 1].
<b>nc</b>	[array_like] Noncentrality parameter. Should be in range (0, 1e4).
<b>f</b>	[array_like] Quantiles, i.e. the upper limit of integration.

**Returns**

<b>dfd</b>	[float] Degrees of freedom of the denominator sum of squares.
------------	---------------------------------------------------------------

**See also:****ncfdtr**

CDF of the non-central F distribution.

**ncfdtri**

Quantile function; inverse of *ncfdtr* with respect to *f*.

**ncfdtridfn**

Inverse of *ncfdtr* with respect to *dfn*.

**ncfdtrinc**

Inverse of *ncfdtr* with respect to *nc*.

**Notes**

The value of the cumulative noncentral F distribution is not necessarily monotone in either degrees of freedom. There thus may be two values that provide a given CDF value. This routine assumes monotonicity and will find an arbitrary one of the two values.

**Examples**

```
>>> from scipy.special import ncfdtr, ncfdtridfd
```

Compute the CDF for several values of *dfd*:

```
>>> dfd = [1, 2, 3]
>>> p = ncfdtr(2, dfd, 0.25, 15)
>>> p
array([0.8097138 , 0.93020416, 0.96787852])
```

Compute the inverse. We recover the values of *dfd*, as expected:

```
>>> ncfdtridfd(2, p, 0.25, 15)
array([1., 2., 3.])
```

**scipy.special.ncfdtridfn**

```
scipy.special.ncfdtridfn(p, dfd, nc, f) = <ufunc 'ncfdtridfn'>
```

Calculate degrees of freedom (numerator) for the noncentral F-distribution.

This is the inverse with respect to *dfn* of *ncfdtr*. See *ncfdtr* for more details.

**Parameters**

**p** [array\_like] Value of the cumulative distribution function. Must be in the range [0, 1].  
**dfd** [array\_like] Degrees of freedom of the denominator sum of squares. Range (0, inf).  
**nc** [array\_like] Noncentrality parameter. Should be in range (0, 1e4).  
**f** [float] Quantiles, i.e. the upper limit of integration.

**Returns**

**dfn** [float] Degrees of freedom of the numerator sum of squares.

**See also:**

**ncfdtr**

CDF of the non-central F distribution.

**ncfdtri**

Quantile function; inverse of *ncfdtr* with respect to *f*.

**ncfdtridfd**

Inverse of *ncfdtr* with respect to *dfd*.

**ncfdtrinc**

Inverse of *ncfdtr* with respect to *nc*.

**Notes**

The value of the cumulative noncentral F distribution is not necessarily monotone in either degrees of freedom. There thus may be two values that provide a given CDF value. This routine assumes monotonicity and will find an arbitrary one of the two values.

**Examples**

```
>>> from scipy.special import ncfdtr, ncfdtridfn
```

Compute the CDF for several values of *dfn*:

```
>>> dfn = [1, 2, 3]
>>> p = ncfdtr(dfn, 2, 0.25, 15)
>>> p
array([0.92562363, 0.93020416, 0.93188394])
```

Compute the inverse. We recover the values of *dfn*, as expected:

```
>>> ncfdtridfn(p, 2, 0.25, 15)
array([1., 2., 3.])
```

**scipy.special.ncfdtri**

`scipy.special.ncfdtri(dfn, dfd, nc, p) = <ufunc 'ncfdtri'>`

Inverse with respect to *f* of the CDF of the non-central F distribution.

See *ncfdtr* for more details.

**Parameters**

**dfn** [array\_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).

**dfd** [array\_like] Degrees of freedom of the denominator sum of squares. Range (0, inf).  
**nc** [array\_like] Noncentrality parameter. Should be in range (0, 1e4).  
**p** [array\_like] Value of the cumulative distribution function. Must be in the range [0, 1].

**Returns**

**f** [float] Quantiles, i.e. the upper limit of integration.

**See also:****ncfdtr**

CDF of the non-central F distribution.

**ncfdtridfd**

Inverse of *ncfdtr* with respect to *dfd*.

**ncfdtridfn**

Inverse of *ncfdtr* with respect to *dfn*.

**ncfdtrinc**

Inverse of *ncfdtr* with respect to *nc*.

**Examples**

```
>>> from scipy.special import ncfdtr, ncfdtri
```

Compute the CDF for several values of *f*:

```
>>> f = [0.5, 1, 1.5]
>>> p = ncfdtr(2, 3, 1.5, f)
>>> p
array([0.20782291, 0.36107392, 0.47345752])
```

Compute the inverse. We recover the values of *f*, as expected:

```
>>> ncfdtri(2, 3, 1.5, p)
array([0.5, 1. , 1.5])
```

**scipy.special.ncfdtrinc**

`scipy.special.ncfdtrinc(dfn, dfd, p, f) = <ufunc 'ncfdtrinc'>`

Calculate non-centrality parameter for non-central F distribution.

This is the inverse with respect to *nc* of *ncfdtr*. See *ncfdtr* for more details.

**Parameters**

**dfn** [array\_like] Degrees of freedom of the numerator sum of squares. Range (0, inf).  
**dfd** [array\_like] Degrees of freedom of the denominator sum of squares. Range (0, inf).  
**p** [array\_like] Value of the cumulative distribution function. Must be in the range [0, 1].  
**f** [array\_like] Quantiles, i.e. the upper limit of integration.

**Returns**

**nc** [float] Noncentrality parameter.

**See also:**

**ncfdtr**

CDF of the non-central F distribution.

**ncfdtri**

Quantile function; inverse of *ncfdtr* with respect to *f*.

**ncfdtridfd**

Inverse of *ncfdtr* with respect to *dfd*.

**ncfdtridfn**

Inverse of *ncfdtr* with respect to *dfn*.

**Examples**

```
>>> from scipy.special import ncfdtr, ncfdtrinc
```

Compute the CDF for several values of *nc*:

```
>>> nc = [0.5, 1.5, 2.0]
>>> p = ncfdtr(2, 3, nc, 15)
>>> p
array([0.96309246, 0.94327955, 0.93304098])
```

Compute the inverse. We recover the values of *nc*, as expected:

```
>>> ncfdtrinc(2, 3, p, 15)
array([0.5, 1.5, 2.])
```

**scipy.special.nctdtr**

`scipy.special.nctdtr(df, nc, t) = <ufunc 'nctdtr'>`

Cumulative distribution function of the non-central *t* distribution.

**Parameters**

**df** [array\_like] Degrees of freedom of the distribution. Should be in range (0, inf).  
**nc** [array\_like] Noncentrality parameter. Should be in range (-1e6, 1e6).  
**t** [array\_like] Quantiles, i.e. the upper limit of integration.

**Returns**

**cdf** [float or ndarray] The calculated CDF. If all inputs are scalar, the return will be a float. Otherwise it will be an array.

**See also:**

**nctdtrit**

Inverse CDF (iCDF) of the non-central *t* distribution.

**nctdtridf**

Calculate degrees of freedom, given CDF and iCDF values.

**nctdtrinc**

Calculate non-centrality parameter, given CDF iCDF values.

## Examples

```
>>> from scipy import special
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

Plot the CDF of the non-central t distribution, for  $nc=0$ . Compare with the t-distribution from `scipy.stats`:

```
>>> x = np.linspace(-5, 5, num=500)
>>> df = 3
>>> nct_stats = stats.t.cdf(x, df)
>>> nct_special = special.nctdtr(df, 0, x)
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, nct_stats, 'b-', lw=3)
>>> ax.plot(x, nct_special, 'r-')
>>> plt.show()
```

### `scipy.special.nctdtridf`

`scipy.special.nctdtridf(p, nc, t) = <ufunc 'nctdtridf'>`

Calculate degrees of freedom for non-central t distribution.

See `nctdtr` for more details.

#### Parameters

<b>p</b>	[array_like] CDF values, in range (0, 1].
<b>nc</b>	[array_like] Noncentrality parameter. Should be in range (-1e6, 1e6).
<b>t</b>	[array_like] Quantiles, i.e. the upper limit of integration.

### `scipy.special.nctdtrit`

`scipy.special.nctdtrit(df, nc, p) = <ufunc 'nctdtrit'>`

Inverse cumulative distribution function of the non-central t distribution.

See `ncdtr` for more details.

**Parameters**

- df** [array\_like] Degrees of freedom of the distribution. Should be in range (0, inf).
- nc** [array\_like] Noncentrality parameter. Should be in range (-1e6, 1e6).
- p** [array\_like] CDF values, in range (0, 1].

**scipy.special.ncdtrinc**

`scipy.special.ncdtrinc(df, p, t) = <ufunc 'ncdtrinc'>`

Calculate non-centrality parameter for non-central t distribution.

See `ncdtr` for more details.

**Parameters**

- df** [array\_like] Degrees of freedom of the distribution. Should be in range (0, inf).
- p** [array\_like] CDF values, in range (0, 1].
- t** [array\_like] Quantiles, i.e. the upper limit of integration.

**scipy.special.nrdtrimn**

`scipy.special.nrdtrimn(p, x, std) = <ufunc 'nrdtrimn'>`

Calculate mean of normal distribution given other params.

**Parameters**

- p** [array\_like] CDF values, in range (0, 1].
- x** [array\_like] Quantiles, i.e. the upper limit of integration.
- std** [array\_like] Standard deviation.

**Returns**

- mn** [float or ndarray] The mean of the normal distribution.

**See also:**

`nrdtrimn`, `ndtr`

**scipy.special.nrdtrisd**

`scipy.special.nrdtrisd(p, x, mn) = <ufunc 'nrdtrisd'>`

Calculate standard deviation of normal distribution given other params.

**Parameters**

- p** [array\_like] CDF values, in range (0, 1].
- x** [array\_like] Quantiles, i.e. the upper limit of integration.
- mn** [float or ndarray] The mean of the normal distribution.

**Returns**

- std** [array\_like] Standard deviation.

**See also:**

`ndtr`

**scipy.special.pdtr**

`scipy.special.pdtr(k, m) = <ufunc 'pdtr'>`  
 Poisson cumulative distribution function

Returns the sum of the first  $k$  terms of the Poisson distribution:  $\sum(\exp(-m) * m^{**j} / j!, j=0..k) = \text{gammaincc}(k+1, m)$ . Arguments must both be positive and  $k$  an integer.

**scipy.special.pdtrc**

`scipy.special.pdtrc(k, m) = <ufunc 'pdtrc'>`  
 Poisson survival function

Returns the sum of the terms from  $k+1$  to infinity of the Poisson distribution:  $\sum(\exp(-m) * m^{**j} / j!, j=k+1..inf) = \text{gammainc}(k+1, m)$ . Arguments must both be positive and  $k$  an integer.

**scipy.special.pdtri**

`scipy.special.pdtri(k, y) = <ufunc 'pdtri'>`  
 Inverse to `pdtr` vs  $m$

Returns the Poisson variable  $m$  such that the sum from 0 to  $k$  of the Poisson density is equal to the given probability  $y$ : calculated by `gammaincinv(k+1, y)`.  $k$  must be a nonnegative integer and  $y$  between 0 and 1.

**scipy.special.pdtrik**

`scipy.special.pdtrik(p, m) = <ufunc 'pdtrik'>`  
 Inverse to `pdtr` vs  $k$

Returns the quantile  $k$  such that `pdtr(k, m) = p`

**scipy.special.stdtr**

`scipy.special.stdtr(df, t) = <ufunc 'stdtr'>`  
 Student t distribution cumulative distribution function

Returns the integral from minus infinity to  $t$  of the Student t distribution with  $df > 0$  degrees of freedom:

```
gamma((df+1)/2) / (sqrt(df*pi) * gamma(df/2)) *
integral((1+x**2/df)**(-df/2-1/2), x=-inf..t)
```

**scipy.special.stdtridf**

`scipy.special.stdtridf(p, t) = <ufunc 'stdtridf'>`  
 Inverse of `stdtr` vs  $df$

Returns the argument  $df$  such that `stdtr(df, t)` is equal to  $p$ .

**scipy.special.stdtrit**

`scipy.special.stdtrit(df, p) = <ufunc 'stdtrit'>`  
 Inverse of `stdtr` vs  $t$

Returns the argument  $t$  such that `stdtr(df, t)` is equal to  $p$ .

**scipy.special.chdtr**

`scipy.special.chdtr(v, x) = <ufunc 'chdtr'>`  
 Chi square cumulative distribution function

Returns the area under the left hand tail (from 0 to  $x$ ) of the Chi square probability density function with  $v$  degrees of freedom:

```
1 / (2**(v/2) * gamma(v/2)) * integral(t**(v/2-1) * exp(-t/2), t=0..x)
```

### scipy.special.chdtrc

`scipy.special.chdtrc(v, x) = <ufunc 'chdtrc'>`

Chi square survival function

Returns the area under the right hand tail (from  $x$  to infinity) of the Chi square probability density function with  $v$  degrees of freedom:

```
1 / (2**(v/2) * gamma(v/2)) * integral(t**(v/2-1) * exp(-t/2), t=x..inf)
```

### scipy.special.chdtri

`scipy.special.chdtri(v, p) = <ufunc 'chdtri'>`

Inverse to `chdtrc`

Returns the argument  $x$  such that `chdtrc(v, x) == p`.

### scipy.special.chdtriv

`scipy.special.chdtriv(p, x) = <ufunc 'chdtriv'>`

Inverse to `chdtr` vs  $v$

Returns the argument  $v$  such that `chdtr(v, x) == p`.

### scipy.special.ndtr

`scipy.special.ndtr(x) = <ufunc 'ndtr'>`

Gaussian cumulative distribution function.

Returns the area under the standard Gaussian probability density function, integrated from minus infinity to  $x$

$$\frac{1}{\sqrt{2\pi}} \int_{-\infty}^x \exp(-t^2/2) dt$$

#### Parameters

**x** [array\_like, real or complex] Argument

#### Returns

**ndarray** The value of the normal CDF evaluated at  $x$

See also:

`erf`, `erfc`, `scipy.stats.norm`, `log_ndtr`

### scipy.special.log\_ndtr

`scipy.special.log_ndtr(x) = <ufunc 'log_ndtr'>`

Logarithm of Gaussian cumulative distribution function.

Returns the log of the area under the standard Gaussian probability density function, integrated from minus infinity to  $x$ :

```
log(1/sqrt(2*pi) * integral(exp(-t**2 / 2), t=-inf..x))
```

#### Parameters

**x** [array\_like, real or complex] Argument

**Returns**

**ndarray** The value of the log of the normal CDF evaluated at  $x$

**See also:**

*erf, erfc, scipy.stats.norm, ndtr*

**scipy.special.ndtri**

`scipy.special.ndtri(y) = <ufunc 'ndtri'>`  
Inverse of *ndtr* vs  $x$

Returns the argument  $x$  for which the area under the Gaussian probability density function (integrated from minus infinity to  $x$ ) is equal to  $y$ .

**scipy.special.chndtr**

`scipy.special.chndtr(x, df, nc) = <ufunc 'chndtr'>`  
Non-central chi square cumulative distribution function

**scipy.special.chndtridf**

`scipy.special.chndtridf(x, p, nc) = <ufunc 'chndtridf'>`  
Inverse to *chndtr* vs  $df$

**scipy.special.chndtrinc**

`scipy.special.chndtrinc(x, df, p) = <ufunc 'chndtrinc'>`  
Inverse to *chndtr* vs  $nc$

**scipy.special.chndtrix**

`scipy.special.chndtrix(p, df, nc) = <ufunc 'chndtrix'>`  
Inverse to *chndtr* vs  $x$

**scipy.special.smirnov**

`scipy.special.smirnov(n, d) = <ufunc 'smirnov'>`  
Kolmogorov-Smirnov complementary cumulative distribution function

Returns the exact Kolmogorov-Smirnov complementary cumulative distribution function,(aka the Survival Function) of  $D_{n+}$  (or  $D_{n-}$ ) for a one-sided test of equality between an empirical and a theoretical distribution. It is equal to the probability that the maximum difference between a theoretical distribution and an empirical one based on  $n$  samples is greater than  $d$ .

**Parameters**

**n** [int] Number of samples  
**d** [float array\_like] Deviation between the Empirical CDF (ECDF) and the target CDF.

**Returns**

**float** The value(s) of `smirnov(n, d)`,  $\text{Prob}(D_{n+} \geq d)$  (Also  $\text{Prob}(D_{n-} \geq d)$ )

**See also:****smirnovi**

The Inverse Survival Function for the distribution

**scipy.stats.ksone**

Provides the functionality as a continuous distribution

*kolmogorov, kolmogi*

## Notes

*smirnov* is used by *stats.kstest* in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historical reasons this function is exposed in *scipy.special*, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the *stats.kstest* distribution.

## Examples

```
>>> from scipy.special import smirnov
```

Show the probability of a gap at least as big as 0, 0.5 and 1.0 for a sample of size 5

```
>>> smirnov(5, [0, 0.5, 1.0])
array([1. , 0.056, 0.])
```

Compare a sample of size 5 drawn from a source  $N(0.5, 1)$  distribution against a target  $N(0, 1)$  CDF.

```
>>> from scipy.stats import norm
>>> n = 5
>>> gendist = norm(0.5, 1) # Normal distribution, mean 0.5, stddev 1
>>> np.random.seed(seed=233423) # Set the seed for reproducibility
>>> x = np.sort(gendist.rvs(size=n))
>>> x
array([-0.20946287, 0.71688765, 0.95164151, 1.44590852, 3.08880533])
>>> target = norm(0, 1)
>>> cdfs = target.cdf(x)
>>> cdfs
array([0.41704346, 0.76327829, 0.82936059, 0.92589857, 0.99899518])
Construct the Empirical CDF and the K-S statistics (Dn+, Dn-, Dn)
>>> ecdfs = np.arange(n+1, dtype=float)/n
>>> cols = np.column_stack([x, ecdfs[1:], cdfs, cdfs - ecdfs[:n],
->ecdfs[1:] - cdfs])
>>> np.set_printoptions(precision=3)
>>> cols
array([[-2.095e-01, 2.000e-01, 4.170e-01, 4.170e-01, -2.170e-01],
 [7.169e-01, 4.000e-01, 7.633e-01, 5.633e-01, -3.633e-01],
 [9.516e-01, 6.000e-01, 8.294e-01, 4.294e-01, -2.294e-01],

->linestyle='dashed', lw=4)
>>> plt.show()

```

### scipy.special.smirnovi

`scipy.special.smirnovi(n, p) = <ufunc 'smirnovi'>`

Inverse to `smirnov`

Returns  $d$  such that `smirnov(n, d) == p`, the critical value corresponding to  $p$ .

#### Parameters

**n** [int] Number of samples  
**p** [float array\_like] Probability

#### Returns

**float** The value(s) of `smirnovi(n, p)`, the critical values.

See also:

**smirnov**

The Survival Function (SF) for the distribution

**scipy.stats.kstone**

Provides the functionality as a continuous distribution

*kolmogorov, kolmogi, scipy.stats.kstwobign*

**Notes**

*smirnov* is used by *stats.kstest* in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historical reasons this function is exposed in *scipy.special*, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the *stats.kstone* distribution.

**scipy.special.kolmogorov**

`scipy.special.kolmogorov(y) = <ufunc 'kolmogorov'>`

Complementary cumulative distribution (Survival Function) function of Kolmogorov distribution.

Returns the complementary cumulative distribution function of Kolmogorov's limiting distribution ( $D_n \cdot \sqrt{n}$  as  $n$  goes to infinity) of a two-sided test for equality between an empirical and a theoretical distribution. It is equal to the (limit as  $n \rightarrow \infty$  of the) probability that  $\sqrt{n} \cdot \max \text{ absolute deviation} > y$ .

**Parameters**

**y** [float array\_like] Absolute deviation between the Empirical CDF (ECDF) and the target CDF, multiplied by  $\sqrt{n}$ .

**Returns**

**float** The value(s) of `kolmogorov(y)`

**See also:**

**kolmogi**

The Inverse Survival Function for the distribution

**scipy.stats.kstwobign**

Provides the functionality as a continuous distribution

*smirnov, smirnovi*

**Notes**

*kolmogorov* is used by *stats.kstest* in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historical reasons this function is exposed in *scipy.special*, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the *stats.kstwobign* distribution.

## Examples

Show the probability of a gap at least as big as 0, 0.5 and 1.0.

```
>>> from scipy.special import kolmogorov
>>> from scipy.stats import kstwobign
>>> kolmogorov([0, 0.5, 1.0])
array([1. , 0.96394524, 0.26999967])
```

Compare a sample of size 1000 drawn from a Laplace(0, 1) distribution against the target distribution, a Normal(0, 1) distribution.

```
>>> from scipy.stats import norm, laplace
>>> n = 1000
>>> np.random.seed(seed=233423)
>>> lap01 = laplace(0, 1)
>>> x = np.sort(lap01.rvs(n))
>>> np.mean(x), np.std(x)
(-0.083073685397609842, 1.3676426568399822)
```

Construct the Empirical CDF and the K-S statistic  $D_n$ .

```
>>> target = norm(0,1) # Normal mean 0, stddev 1
>>> cdfs = target.cdf(x)
>>> ecdfs = np.arange(n+1, dtype=float)/n
>>> gaps = np.column_stack([cdfs - ecdfs[:n], ecdfs[1:] - cdfs])
>>> Dn = np.max(gaps)
>>> Kn = np.sqrt(n) * Dn
>>> print('Dn=%f, sqrt(n)*Dn=%f' % (Dn, Kn))
Dn=0.058286, sqrt(n)*Dn=1.843153
>>> print(chr(10).join(['For a sample of size n drawn from a N(0, 1) ↵
↵distribution:',
... ' the approximate Kolmogorov probability that sqrt(n)*Dn>=%f is %f
↵' % (Kn, kolmogorov(Kn)),
... ' the approximate Kolmogorov probability that sqrt(n)*Dn<=%f is %f
↵' % (Kn, kstwobign.cdf(Kn))]))
For a sample of size n drawn from a N(0, 1) distribution:
the approximate Kolmogorov probability that sqrt(n)*Dn>=1.843153 is 0.
↵002240
the approximate Kolmogorov probability that sqrt(n)*Dn<=1.843153 is 0.
↵997760
```

Plot the Empirical CDF against the target  $N(0, 1)$  CDF.

```
>>> import matplotlib.pyplot as plt
>>> plt.step(np.concatenate([[-3], x]), ecdfs, where='post', label=
↵'Empirical CDF')
>>> x3 = np.linspace(-3, 3, 100)
>>> plt.plot(x3, target.cdf(x3), label='CDF for N(0, 1)')
>>> plt.ylim([0, 1]); plt.grid(True); plt.legend();
>>> # Add vertical lines marking Dn+ and Dn-
>>> iminus, iplus = np.argmax(gaps, axis=0)
>>> plt.vlines([x[iminus]], ecdfs[iminus], cdfs[iminus], color='r', ↵
↵linestyle='dashed', lw=4)
```

(continues on next page)

(continued from previous page)

```
>>> plt.vlines([x[iplus]], cdfs[iplus], ecdfs[iplus+1], color='r', lw=4,
->linestyle='dashed', lw=4)
>>> plt.show()
```

### scipy.special.kolmogi

`scipy.special.kolmogi(p)` = <ufunc 'kolmogi'>

Inverse Survival Function of Kolmogorov distribution

It is the inverse function to *kolmogorov*. Returns  $y$  such that  $\text{kolmogorov}(y) == p$ .

#### Parameters

**p** [float array\_like] Probability

#### Returns

**float** The value(s) of `kolmogi(p)`

See also:

#### `kolmogorov`

The Survival Function for the distribution

#### `scipy.stats.kstwobign`

Provides the functionality as a continuous distribution

*smirnov*, *smirnovi*

### Notes

*kolmogorov* is used by *stats.kstest* in the application of the Kolmogorov-Smirnov Goodness of Fit test. For historical reasons this function is exposed in *scipy.special*, but the recommended way to achieve the most accurate CDF/SF/PDF/PPF/ISF computations is to use the *stats.kstwobign* distribution.

## Examples

```
>>> from scipy.special import kolmogi
>>> kolmogi([0, 0.1, 0.25, 0.5, 0.75, 0.9, 1.0])
array([inf, 1.22384787, 1.01918472, 0.82757356, 0.67644769,
 0.57117327, 0.])
```

### scipy.special.tklmbda

`scipy.special.tklmbda(x, lambda) = <ufunc 'tklmbda'>`  
 Tukey-Lambda cumulative distribution function

### scipy.special.logit

`scipy.special.logit(x) = <ufunc 'logit'>`  
 Logit ufunc for ndarrays.

The logit function is defined as  $\text{logit}(p) = \log(p/(1-p))$ . Note that  $\text{logit}(0) = -\text{inf}$ ,  $\text{logit}(1) = \text{inf}$ , and  $\text{logit}(p)$  for  $p < 0$  or  $p > 1$  yields nan.

#### Parameters

**x** [ndarray] The ndarray to apply logit to element-wise.

#### Returns

**out** [ndarray] An ndarray of the same shape as x. Its entries are logit of the corresponding entry of x.

#### See also:

*expit*

#### Notes

As a ufunc logit takes a number of optional keyword arguments. For more information see [ufuncs](#)

New in version 0.10.0.

## Examples

```
>>> from scipy.special import logit, expit
```

```
>>> logit([0, 0.25, 0.5, 0.75, 1])
array([-inf, -1.09861229, 0. , 1.09861229, inf])
```

*expit* is the inverse of *logit*:

```
>>> expit(logit([0.1, 0.75, 0.999]))
array([0.1 , 0.75 , 0.999])
```

Plot  $\text{logit}(x)$  for  $x$  in  $[0, 1]$ :

```

>>> import matplotlib.pyplot as plt
>>> x = np.linspace(0, 1, 501)
>>> y = logit(x)
>>> plt.plot(x, y)
>>> plt.grid()
>>> plt.ylim(-6, 6)
>>> plt.xlabel('x')
>>> plt.title('logit(x)')
>>> plt.show()

```

### scipy.special.expit

`scipy.special.expit(x)` = <ufunc 'expit'>

Expit (a.k.a. logistic sigmoid) ufunc for ndarrays.

The expit function, also known as the logistic sigmoid function, is defined as  $\text{expit}(x) = 1 / (1 + \exp(-x))$ . It is the inverse of the logit function.

#### Parameters

**x** [ndarray] The ndarray to apply expit to element-wise.

#### Returns

**out** [ndarray] An ndarray of the same shape as x. Its entries are *expit* of the corresponding entry of x.

#### See also:

*logit*

#### Notes

As a ufunc expit takes a number of optional keyword arguments. For more information see *ufuncs*

New in version 0.10.0.

## Examples

```
>>> from scipy.special import expit, logit
```

```
>>> expit([-np.inf, -1.5, 0, 1.5, np.inf])
array([0. , 0.18242552, 0.5 , 0.81757448, 1.])
```

*logit* is the inverse of *expit*:

```
>>> logit(expit([-2.5, 0, 3.1, 5.0]))
array([-2.5, 0. , 3.1, 5.])
```

Plot *expit*(*x*) for *x* in [-6, 6]:

```
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-6, 6, 121)
>>> y = expit(x)
>>> plt.plot(x, y)
>>> plt.grid()
>>> plt.xlim(-6, 6)
>>> plt.xlabel('x')
>>> plt.title('expit(x)')
>>> plt.show()
```

## scipy.special.boxcox

`scipy.special.boxcox(x, lambda)` = <ufunc 'boxcox'>

Compute the Box-Cox transformation.

The Box-Cox transformation is:

```
y = (x**lambda - 1) / lambda if lambda != 0
 log(x) if lambda == 0
```

Returns *nan* if *x* < 0. Returns *-inf* if *x* == 0 and *lambda* < 0.

**Parameters**

**x** [array\_like] Data to be transformed.  
**lambda** [array\_like] Power parameter of the Box-Cox transform.

**Returns**

**y** [array] Transformed data.

**Notes**

New in version 0.14.0.

**Examples**

```
>>> from scipy.special import boxcox
>>> boxcox([1, 4, 10], 2.5)
array([0. , 12.4 , 126.09110641])
>>> boxcox(2, [0, 1, 2])
array([0.69314718, 1. , 1.5])
```

**scipy.special.boxcox1p**

`scipy.special.boxcox1p(x, lambda) = <ufunc 'boxcox1p'>`

Compute the Box-Cox transformation of  $1 + x$ .

The Box-Cox transformation computed by `boxcox1p` is:

```
y = ((1+x)**lambda - 1) / lambda if lambda != 0
 log(1+x) if lambda == 0
```

Returns *nan* if  $x < -1$ . Returns *-inf* if  $x == -1$  and  $lambda < 0$ .

**Parameters**

**x** [array\_like] Data to be transformed.  
**lambda** [array\_like] Power parameter of the Box-Cox transform.

**Returns**

**y** [array] Transformed data.

**Notes**

New in version 0.14.0.

**Examples**

```
>>> from scipy.special import boxcox1p
>>> boxcox1p(1e-4, [0, 0.5, 1])
array([9.99950003e-05, 9.99975001e-05, 1.00000000e-04])
>>> boxcox1p([0.01, 0.1], 0.25)
array([0.00996272, 0.09645476])
```

**scipy.special.inv\_boxcox**

`scipy.special.inv_boxcox(y, lmbda) = <ufunc 'inv_boxcox'>`  
 Compute the inverse of the Box-Cox transformation.

Find  $x$  such that:

```
y = (x**lmbda - 1) / lmbda if lmbda != 0
 log(x) if lmbda == 0
```

**Parameters**

**y** [array\_like] Data to be transformed.  
**lmbda** [array\_like] Power parameter of the Box-Cox transform.

**Returns**

**x** [array] Transformed data.

**Notes**

New in version 0.16.0.

**Examples**

```
>>> from scipy.special import boxcox, inv_boxcox
>>> y = boxcox([1, 4, 10], 2.5)
>>> inv_boxcox(y, 2.5)
array([1., 4., 10.]
```

**scipy.special.inv\_boxcox1p**

`scipy.special.inv_boxcox1p(y, lmbda) = <ufunc 'inv_boxcox1p'>`  
 Compute the inverse of the Box-Cox transformation.

Find  $x$  such that:

```
y = ((1+x)**lmbda - 1) / lmbda if lmbda != 0
 log(1+x) if lmbda == 0
```

**Parameters**

**y** [array\_like] Data to be transformed.  
**lmbda** [array\_like] Power parameter of the Box-Cox transform.

**Returns**

**x** [array] Transformed data.

**Notes**

New in version 0.16.0.

## Examples

```
>>> from scipy.special import boxcox1p, inv_boxcox1p
>>> y = boxcox1p([1, 4, 10], 2.5)
>>> inv_boxcox1p(y, 2.5)
array([1., 4., 10.]
```

## scipy.special.owens\_t

`scipy.special.owens_t(h, a) = <ufunc 'owens_t'>`

Owen's T Function.

The function  $T(h, a)$  gives the probability of the event  $(X > h \text{ and } 0 < Y < a * X)$  where  $X$  and  $Y$  are independent standard normal random variables.

### Parameters

**h:** `array_like`  
Input value.

**a:** `array_like`  
Input value.

### Returns

**t:** `scalar or ndarray`  
Probability of the event  $(X > h \text{ and } 0 < Y < a * X)$ , where  $X$  and  $Y$  are independent standard normal random variables.

## References

[1]

## Examples

```
>>> from scipy import special
>>> a = 3.5
>>> h = 0.78
>>> special.owens_t(h, a)
0.10877216734852274
```

## Information Theory Functions

<code>entr(x)</code>	Elementwise function for computing entropy.
<code>rel_entr(x, y)</code>	Elementwise function for computing relative entropy.
<code>kl_div(x, y)</code>	Elementwise function for computing Kullback-Leibler divergence.
<code>huber(delta, r)</code>	Huber loss function.
<code>pseudo_huber(delta, r)</code>	Pseudo-Huber loss function.

**scipy.special.entr**

`scipy.special.entr(x) = <ufunc 'entr'>`

Elementwise function for computing entropy.

$$\text{entr}(x) = \begin{cases} -x \log(x) & x > 0 \\ 0 & x = 0 \\ -\infty & \text{otherwise} \end{cases}$$

**Parameters**

**x** [ndarray] Input array.

**Returns**

**res** [ndarray] The value of the elementwise entropy function at the given points  $x$ .

**See also:**

`kl_div`, `rel_entr`

**Notes**

This function is concave.

New in version 0.15.0.

**scipy.special.rel\_entr**

`scipy.special.rel_entr(x, y) = <ufunc 'rel_entr'>`

Elementwise function for computing relative entropy.

$$\text{rel\_entr}(x, y) = \begin{cases} x \log(x/y) & x > 0, y > 0 \\ 0 & x = 0, y \geq 0 \\ \infty & \text{otherwise} \end{cases}$$

**Parameters**

**x** [ndarray] First input array.

**y** [ndarray] Second input array.

**Returns**

**res** [ndarray] Output array.

**See also:**

`entr`, `kl_div`

**Notes**

This function is jointly convex in  $x$  and  $y$ .

New in version 0.15.0.

**scipy.special.kl\_div**`scipy.special.kl_div(x, y) = <ufunc 'kl_div'>`

Elementwise function for computing Kullback-Leibler divergence.

$$\text{kl\_div}(x, y) = \begin{cases} x \log(x/y) - x + y & x > 0, y > 0 \\ y & x = 0, y \geq 0 \\ \infty & \text{otherwise} \end{cases}$$

**Parameters**

**x** [ndarray] First input array.  
**y** [ndarray] Second input array.

**Returns**

**res** [ndarray] Output array.

**See also:**`entr, rel_entr`**Notes**This function is non-negative and is jointly convex in  $x$  and  $y$ .

New in version 0.15.0.

**scipy.special.huber**`scipy.special.huber(delta, r) = <ufunc 'huber'>`

Huber loss function.

$$\text{huber}(\delta, r) = \begin{cases} \infty & \delta < 0 \\ \frac{1}{2}r^2 & 0 \leq \delta, |r| \leq \delta \\ \delta(|r| - \frac{1}{2}\delta) & \text{otherwise} \end{cases}$$

**Parameters**

**delta** [ndarray] Input array, indicating the quadratic vs. linear loss changepoint.  
**r** [ndarray] Input array, possibly representing residuals.

**Returns**

**res** [ndarray] The computed Huber loss function values.

**Notes**This function is convex in  $r$ .

New in version 0.15.0.

**scipy.special.pseudo\_huber**

`scipy.special.pseudo_huber(delta, r) = <ufunc 'pseudo_huber'>`  
 Pseudo-Huber loss function.

$$\text{pseudo\_huber}(\delta, r) = \delta^2 \left( \sqrt{1 + \left(\frac{r}{\delta}\right)^2} - 1 \right)$$

**Parameters**

**delta** [ndarray] Input array, indicating the soft quadratic vs. linear loss changepoint.  
**r** [ndarray] Input array, possibly representing residuals.

**Returns**

**res** [ndarray] The computed Pseudo-Huber loss function values.

**Notes**

This function is convex in  $r$ .

New in version 0.15.0.

**Gamma and Related Functions**

<code>gamma(z)</code>	Gamma function.
<code>gammaaln(x, /[, out, where, casting, order, ...])</code>	Logarithm of the absolute value of the Gamma function.
<code>loggamma(z[, out])</code>	Principal branch of the logarithm of the Gamma function.
<code>gamma<sub>sgn</sub>(x)</code>	Sign of the gamma function.
<code>gamma<sub>inc</sub>(a, x)</code>	Regularized lower incomplete gamma function.
<code>gamma<sub>inc</sub>inv(a, y)</code>	Inverse to <code>gamma<sub>inc</sub></code>
<code>gamma<sub>inc</sub>cc(a, x)</code>	Regularized upper incomplete gamma function.
<code>gamma<sub>inc</sub>ccinv(a, y)</code>	Inverse to <code>gamma<sub>inc</sub>cc</code>
<code>beta(a, b)</code>	Beta function.
<code>betaln(a, b)</code>	Natural logarithm of absolute value of beta function.
<code>beta<sub>inc</sub>(a, b, x)</code>	Incomplete beta integral.
<code>beta<sub>inc</sub>inv(a, b, y)</code>	Inverse function to beta integral.
<code>psi(z[, out])</code>	The digamma function.
<code>rgamma(z)</code>	Gamma function inverted
<code>polygamma(n, x)</code>	Polygamma function $n$ .
<code>multigammaln(a, d)</code>	Returns the log of multivariate gamma, also sometimes called the generalized gamma.
<code>digamma(z[, out])</code>	The digamma function.
<code>poch(z, m)</code>	Rising factorial $(z)_m$

**scipy.special.gamma**

`scipy.special.gamma(z) = <ufunc 'gamma'>`  
 Gamma function.

$$\Gamma(z) = \int_0^{\infty} x^{z-1} e^{-x} dx = (z-1)!$$

The gamma function is often referred to as the generalized factorial since  $z * \text{gamma}(z) = \text{gamma}(z+1)$  and  $\text{gamma}(n+1) = n!$  for natural number  $n$ .

**Parameters****z** [float or complex array\_like]**Returns****float or complex**The value(s) of  $\gamma(z)$ **Examples**

```
>>> from scipy.special import gamma, factorial
```

```
>>> gamma([0, 0.5, 1, 5])
array([inf, 1.77245385, 1. , 24.])
```

```
>>> z = 2.5 + 1j
>>> gamma(z)
(0.77476210455108352+0.70763120437959293j)
>>> gamma(z+1), z*gamma(z) # Recurrence property
((1.2292740569981171+2.5438401155000685j),
 (1.2292740569981158+2.5438401155000658j))
```

```
>>> gamma(0.5)**2 # gamma(0.5) = sqrt(pi)
3.1415926535897927
```

Plot  $\gamma(x)$  for real  $x$ 

```
>>> x = np.linspace(-3.5, 5.5, 2251)
>>> y = gamma(x)
```

```
>>> import matplotlib.pyplot as plt
>>> plt.plot(x, y, 'b', alpha=0.6, label='gamma(x)')
>>> k = np.arange(1, 7)
>>> plt.plot(k, factorial(k-1), 'k*', alpha=0.6,
... label='(x-1)!, x = 1, 2, ...')
>>> plt.xlim(-3.5, 5.5)
>>> plt.ylim(-10, 25)
>>> plt.grid()
>>> plt.xlabel('x')
>>> plt.legend(loc='lower right')
>>> plt.show()
```

**scipy.special.gammaln**

`scipy.special.gammaln(x, /, out=None, *, where=True, casting='same_kind', order='K', dtype=None, subok=True[, signature, extobj]) = <ufunc 'gammaln'>`

Logarithm of the absolute value of the Gamma function.

**Parameters****x** [array-like] Values on the real line at which to compute `gammaln`**Returns****gammaln** [ndarray] Values of `gammaln` at  $x$ .

See also:

`gamma.sgn`

sign of the gamma function

`loggamma`

principal branch of the logarithm of the gamma function

## Notes

When used in conjunction with `gamma.sgn`, this function is useful for working in logspace on the real axis without having to deal with complex numbers, via the relation  $\exp(\text{gamma.ln}(x)) = \text{gamma.sgn}(x) * \text{gamma}(x)$ .

For complex-valued log-gamma, use `loggamma` instead of `gamma.ln`.

## `scipy.special.loggamma`

`scipy.special.loggamma(z, out=None) = <ufunc 'loggamma'>`

Principal branch of the logarithm of the Gamma function.

Defined to be  $\log(\Gamma(x))$  for  $x > 0$  and extended to the complex plane by analytic continuation. The function has a single branch cut on the negative real axis.

New in version 0.18.0.

### Parameters

**z** [array-like] Values in the complex plain at which to compute `loggamma`

**out** [ndarray, optional] Output array for computed values of `loggamma`

### Returns

**loggamma** [ndarray] Values of `loggamma` at `z`.

See also:

**gamma1n**

logarithm of the absolute value of the Gamma function

**gamma1sgn**

sign of the gamma function

**Notes**

It is not generally true that  $\log \Gamma(z) = \log(\Gamma(z))$ , though the real parts of the functions do agree. The benefit of not defining *loggamma* as  $\log(\Gamma(z))$  is that the latter function has a complicated branch cut structure whereas *loggamma* is analytic except for on the negative real axis.

The identities

$$\begin{aligned} \exp(\log \Gamma(z)) &= \Gamma(z) \\ \log \Gamma(z + 1) &= \log(z) + \log \Gamma(z) \end{aligned}$$

make *loggamma* useful for working in complex logspace.

On the real line *loggamma* is related to *gamma1n* via  $\exp(\loggamma(x + 0j)) = \text{gamma1sgn}(x) * \exp(\text{gamma1n}(x))$ , up to rounding error.

The implementation here is based on [hare1997].

**References**

[hare1997]

**scipy.special.gammasgn**

`scipy.special.gammasgn(x) = <ufunc 'gammasgn'>`  
 Sign of the gamma function.

**See also:**

*gamma1n*, *loggamma*

**scipy.special.gammainc**

`scipy.special.gammainc(a, x) = <ufunc 'gammainc'>`  
 Regularized lower incomplete gamma function.

Defined as

$$\frac{1}{\Gamma(a)} \int_0^x t^{a-1} e^{-t} dt$$

for  $a > 0$  and  $x \geq 0$ . The function satisfies the relation  $\text{gammainc}(a, x) + \text{gammaincc}(a, x) = 1$  where *gammaincc* is the regularized upper incomplete gamma function.

**See also:**

**gammaincc**

regularized upper incomplete gamma function

**gammaincinv**

inverse to *gammainc* versus x

**gammainccinv**

inverse to `gammaincc` versus `x`

**Notes**

The implementation largely follows that of [1].

**References**

[1]

**scipy.special.gammaincinv**

`scipy.special.gammaincinv(a, y) = <ufunc 'gammaincinv'>`

Inverse to `gammainc`

Returns `x` such that `gammainc(a, x) = y`.

**scipy.special.gammaincc**

`scipy.special.gammaincc(a, x) = <ufunc 'gammaincc'>`

Regularized upper incomplete gamma function.

Defined as

$$\frac{1}{\Gamma(a)} \int_x^\infty t^{a-1} e^{-t} dt$$

for  $a > 0$  and  $x \geq 0$ . The function satisfies the relation `gammainc(a, x) + gammaincc(a, x) = 1` where `gammainc` is the regularized lower incomplete gamma function.

**See also:**

**gammainc**

regularized lower incomplete gamma function

**gammaincinv**

inverse to `gammainc` versus `x`

**gammainccinv**

inverse to `gammaincc` versus `x`

**Notes**

The implementation largely follows that of [1].

**References**

[1]

**scipy.special.gammaincinv**

`scipy.special.gammaincinv(a, y) = <ufunc 'gammaincinv'>`  
Inverse to `gammaincc`

Returns  $x$  such that `gammaincc(a, x) == y`.

**scipy.special.beta**

`scipy.special.beta(a, b) = <ufunc 'beta'>`  
Beta function.

$$\text{beta}(a, b) = \frac{\text{gamma}(a) * \text{gamma}(b)}{\text{gamma}(a+b)}$$

**scipy.special.betaln**

`scipy.special.betaln(a, b) = <ufunc 'betaln'>`  
Natural logarithm of absolute value of beta function.

Computes  $\ln(\text{abs}(\text{beta}(a, b)))$ .

**scipy.special.betainc**

`scipy.special.betainc(a, b, x) = <ufunc 'betainc'>`  
Incomplete beta integral.

Compute the incomplete beta integral of the arguments, evaluated from zero to  $x$ :

$$\frac{\text{gamma}(a+b)}{\text{gamma}(a) * \text{gamma}(b)} * \int_0^x t^{a-1} (1-t)^{b-1} dt$$

**Notes**

The incomplete beta is also sometimes defined without the terms in gamma, in which case the above definition is the so-called regularized incomplete beta. Under this definition, you can get the incomplete beta by multiplying the result of the scipy function by `beta(a, b)`.

**scipy.special.betaincinv**

`scipy.special.betaincinv(a, b, y) = <ufunc 'betaincinv'>`  
Inverse function to beta integral.

Compute  $x$  such that `betainc(a, b, x) = y`.

**scipy.special.psi**

`scipy.special.psi(z, out=None) = <ufunc 'psi'>`  
The digamma function.

The logarithmic derivative of the gamma function evaluated at  $z$ .

**Parameters**

**z** [array\_like] Real or complex argument.  
**out** [ndarray, optional] Array for the computed values of `psi`.

**Returns**

**digamma** [ndarray] Computed values of `psi`.

## Notes

For large values not close to the negative real axis `psi` is computed using the asymptotic series (5.11.2) from [1]. For small arguments not close to the negative real axis the recurrence relation (5.5.2) from [1] is used until the argument is large enough to use the asymptotic series. For values close to the negative real axis the reflection formula (5.5.4) from [1] is used first. Note that `psi` has a family of zeros on the negative real axis which occur between the poles at nonpositive integers. Around the zeros the reflection formula suffers from cancellation and the implementation loses precision. The sole positive zero and the first negative zero, however, are handled separately by precomputing series expansions using [2], so the function should maintain full accuracy around the origin.

## References

[1], [2]

### `scipy.special.rgamma`

`scipy.special.rgamma(z) = <ufunc 'rgamma'>`  
Gamma function inverted

Returns  $1/\text{gamma}(x)$

### `scipy.special.polygamma`

`scipy.special.polygamma(n, x)`  
Polygamma function  $n$ .

This is the  $n$ th derivative of the digamma (`psi`) function.

#### Parameters

**n** [array\_like of int] The order of the derivative of `psi`.  
**x** [array\_like] Where to evaluate the polygamma function.

#### Returns

**polygamma**  
[ndarray] The result.

## Examples

```
>>> from scipy import special
>>> x = [2, 3, 25.5]
>>> special.polygamma(1, x)
array([0.64493407, 0.39493407, 0.03999467])
>>> special.polygamma(0, x) == special.psi(x)
array([True, True, True], dtype=bool)
```

### `scipy.special.multigammaln`

`scipy.special.multigammaln(a, d)`

Returns the log of multivariate gamma, also sometimes called the generalized gamma.

#### Parameters

**a** [ndarray] The multivariate gamma is computed for each item of  $a$ .  
**d** [int] The dimension of the space of integration.

#### Returns

**res** [ndarray] The values of the log multivariate gamma at the given points  $a$ .

## Notes

The formal definition of the multivariate gamma of dimension  $d$  for a real  $a$  is

$$\Gamma_d(a) = \int_{A>0} e^{-\text{tr}(A)} |A|^{a-(d+1)/2} dA$$

with the condition  $a > (d - 1)/2$ , and  $A > 0$  being the set of all the positive definite matrices of dimension  $d$ . Note that  $a$  is a scalar: the integrand only is multivariate, the argument is not (the function is defined over a subset of the real set).

This can be proven to be equal to the much friendlier equation

$$\Gamma_d(a) = \pi^{d(d-1)/4} \prod_{i=1}^d \Gamma(a - (i - 1)/2).$$

R. J. Muirhead, Aspects of multivariate statistical theory (Wiley Series in probability and mathematical statistics).

## scipy.special.digamma

`scipy.special.digamma(z, out=None) = <ufunc 'psi'>`

The digamma function.

The logarithmic derivative of the gamma function evaluated at  $z$ .

### Parameters

**z** [array\_like] Real or complex argument.  
**out** [ndarray, optional] Array for the computed values of `psi`.

### Returns

**digamma** [ndarray] Computed values of `psi`.

## Notes

For large values not close to the negative real axis `psi` is computed using the asymptotic series (5.11.2) from [1]. For small arguments not close to the negative real axis the recurrence relation (5.5.2) from [1] is used until the argument is large enough to use the asymptotic series. For values close to the negative real axis the reflection formula (5.5.4) from [1] is used first. Note that `psi` has a family of zeros on the negative real axis which occur between the poles at nonpositive integers. Around the zeros the reflection formula suffers from cancellation and the implementation loses precision. The sole positive zero and the first negative zero, however, are handled separately by precomputing series expansions using [2], so the function should maintain full accuracy around the origin.

## References

**scipy.special.poch**

`scipy.special.poch(z, m) = <ufunc 'poch'>`  
 Rising factorial ( $z$ ) <sub>$m$</sub>

The Pochhammer symbol (rising factorial), is defined as

$$(z)_m = \frac{\Gamma(z + m)}{\Gamma(z)}$$

For positive integer  $m$  it reads

$$(z)_m = z(z + 1)\dots(z + m - 1)$$

**Parameters**

**z** [array\_like] (int or float)  
**m** [array\_like] (int or float)

**Returns**

**poch** [ndarray] The value of the function.

**Error Function and Fresnel Integrals**

<code>erf(z)</code>	Returns the error function of complex argument.
<code>erfc(x)</code>	Complementary error function, $1 - \text{erf}(x)$ .
<code>erfcx(x)</code>	Scaled complementary error function, $\exp(x^2) * \text{erfc}(x)$ .
<code>erfi(z)</code>	Imaginary error function, $-i \text{erf}(i z)$ .
<code>erfinv(y)</code>	Inverse of the error function erf.
<code>erfcinv(y)</code>	Inverse of the complementary error function erfc.
<code>wofz(z)</code>	Faddeeva function
<code>dawson(x)</code>	Dawson's integral.
<code>fresnel(z)</code>	Fresnel sin and cos integrals
<code>fresnel_zeros(nt)</code>	Compute nt complex zeros of sine and cosine Fresnel integrals S(z) and C(z).
<code>modfresnelp(x)</code>	Modified Fresnel positive integrals
<code>modfresnelm(x)</code>	Modified Fresnel negative integrals

**scipy.special.erf**

`scipy.special.erf(z) = <ufunc 'erf'>`  
 Returns the error function of complex argument.

It is defined as  $2/\sqrt{\pi} * \text{integral}(\exp(-t^2), t=0..z)$ .

**Parameters**

**x** [ndarray] Input array.

**Returns**

**res** [ndarray] The values of the error function at the given points  $x$ .

**See also:**

`erfc`, `erfinv`, `erfcinv`, `wofz`, `erfcx`, `erfi`

## Notes

The cumulative of the unit normal distribution is given by  $\Phi(z) = 1/2[1 + \text{erf}(z/\sqrt{2})]$ .

>>> plt.xlabel('x')
>>> plt.ylabel('$erfi(x)$')
>>> plt.show()
```

### scipy.special.erfinv

`scipy.special.erfinv`(y)

Inverse of the error function erf.

Computes the inverse of the error function.

In complex domain, there is no unique complex number  $w$  satisfying  $\text{erf}(w)=z$ . This indicates a true inverse function would have multi-value. When the domain restricts to the real,  $-1 < x < 1$ , there is a unique real number satisfying  $\text{erf}(\text{erfinv}(x)) = x$ .

#### Parameters

**y** [ndarray] Argument at which to evaluate. Domain:  $[-1, 1]$

#### Returns

**erfinv** [ndarray] The inverse of erf of y, element-wise

### Examples

- 1) evaluating a float number

```
>>> from scipy import special
>>> special.erfinv(0.5)
0.4769362762044698
```

- 2) evaluating a ndarray

```
>>> from scipy import special
>>> y = np.linspace(-1.0, 1.0, num=10)
>>> special.erfinv(y)
array([-inf, -0.86312307, -0.5407314 , -0.30457019, -0.0987901 ,
 0.0987901 , 0.30457019, 0.5407314 , 0.86312307, inf])
```

**scipy.special.erfcinv**`scipy.special.erfcinv(y)`Inverse of the complementary error function `erfc`.Computes the inverse of the complementary error function `erfc`.

In complex domain, there is no unique complex number  $w$  satisfying  $\text{erfc}(w)=z$ . This indicates a true inverse function would have multi-value. When the domain restricts to the real,  $0 < x < 2$ , there is a unique real number satisfying  $\text{erfc}(\text{erfcinv}(x)) = \text{erfcinv}(\text{erfc}(x))$ .

It is related to inverse of the error function by  $\text{erfcinv}(1-x) = \text{erfinv}(x)$ **Parameters****y** [ndarray] Argument at which to evaluate. Domain: [0, 2]**Returns****erfcinv** [ndarray] The inverse of `erfc` of `y`, element-wise**Examples**

- 1) evaluating a float number

```
>>> from scipy import special
>>> special.erfcinv(0.5)
0.4769362762044698
```

- 2) evaluating a ndarray

```
>>> from scipy import special
>>> y = np.linspace(0.0, 2.0, num=11)
>>> special.erfcinv(y)
array([inf, 0.9061938 , 0.59511608, 0.37080716, 0.17914345,
 -0. , -0.17914345, -0.37080716, -0.59511608, -0.9061938 ,
 -inf])
```

**scipy.special.wofz**`scipy.special.wofz(z) = <ufunc 'wofz'>`

Faddeeva function

Returns the value of the Faddeeva function for complex argument:

```
exp(-z**2) * erfc(-i*z)
```

**See also:***dawsn, erf, erfc, erfcx, erfi***References**

[1]

## Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
```

```
>>> x = np.linspace(-3, 3)
>>> z = special.wofz(x)
```

```
>>> plt.plot(x, z.real, label='wofz(x).real')
>>> plt.plot(x, z.imag, label='wofz(x).imag')
>>> plt.xlabel('x')
>>> plt.legend(framealpha=1, shadow=True)
>>> plt.grid(alpha=0.25)
>>> plt.show()
```

## scipy.special.dawsn

`scipy.special.dawsn(x)` = <ufunc 'dawsn'>  
Dawson's integral.

Computes:

```
exp(-x**2) * integral(exp(t**2), t=0..x).
```

See also:

*wofz*, *erf*, *erfc*, *erfcx*, *erfi*

## References

[1]

## Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-15, 15, num=1000)
>>> plt.plot(x, special.dawsn(x))
>>> plt.xlabel('x')
>>> plt.ylabel('$dawsn(x)$')
>>> plt.show()
```

**scipy.special.fresnel**

`scipy.special.fresnel(z)` = <ufunc 'fresnel'>

Fresnel sin and cos integrals

Defined as:

```
ssa = integral(sin(pi/2 * t**2), t=0..z)
csa = integral(cos(pi/2 * t**2), t=0..z)
```

**Parameters**

**z** [float or complex array\_like] Argument

**Returns**

**ssa, csa** Fresnel sin and cos integral values

**scipy.special.fresnel\_zeros**

`scipy.special.fresnel_zeros(nt)`

Compute  $nt$  complex zeros of sine and cosine Fresnel integrals  $S(z)$  and  $C(z)$ .

**References**

[1]

**scipy.special.modfresnel**

`scipy.special.modfresnel(x)` = <ufunc 'modfresnel'>  
Modified Fresnel positive integrals

**Returns**

**fp**      Integral  $F_+(x)$ :  $\text{integral}(\exp(1j*t*t), t=x..\text{inf})$   
**kp**      Integral  $K_+(x)$ :  $1/\text{sqrt}(\text{pi}) * \exp(-1j*(x*x+\text{pi}/4)) * \text{fp}$

**scipy.special.modfresnelm**

`scipy.special.modfresnelm(x)` = <ufunc 'modfresnelm'>  
Modified Fresnel negative integrals

**Returns**

**fm**      Integral  $F_-(x)$ :  $\text{integral}(\exp(-1j*t*t), t=x..\text{inf})$   
**km**      Integral  $K_-(x)$ :  $1/\text{sqrt}(\text{pi}) * \exp(1j*(x*x+\text{pi}/4)) * \text{fm}$

These are not universal functions:

<code>erf_zeros(nt)</code>	Compute the first $nt$ zero in the first quadrant, ordered by absolute value.
<code>fresnelc_zeros(nt)</code>	Compute $nt$ complex zeros of cosine Fresnel integral $C(z)$ .
<code>fresnels_zeros(nt)</code>	Compute $nt$ complex zeros of sine Fresnel integral $S(z)$ .

**scipy.special.erf\_zeros**

`scipy.special.erf_zeros(nt)`

Compute the first  $nt$  zero in the first quadrant, ordered by absolute value.

Zeros in the other quadrants can be obtained by using the symmetries  $\text{erf}(-z) = \text{erf}(z)$  and  $\text{erf}(\text{conj}(z)) = \text{conj}(\text{erf}(z))$ .

**Parameters**

**nt**      [int] The number of zeros to compute

**Returns****The locations of the zeros of erf**

[ndarray (complex)] Complex values at which zeros of  $\text{erf}(z)$

**References**

[1]

**Examples**

```
>>> from scipy import special
>>> special.erf_zeros(1)
array([1.45061616+1.880943j])
```

Check that erf is (close to) zero for the value returned by `erf_zeros`

```
>>> special.erf(special.erf_zeros(1))
array([4.95159469e-14-1.16407394e-16j])
```

### scipy.special.fresnelc\_zeros

`scipy.special.fresnelc_zeros` (*nt*)  
 Compute *nt* complex zeros of cosine Fresnel integral C(z).

#### References

## Legendre Functions

<code>lpmv</code> ( <i>m</i> , <i>v</i> , <i>x</i> )	Associated Legendre function of integer order and real degree.
<code>sph_harm</code> ( <i>m</i> , <i>n</i> , <i>theta</i> , <i>phi</i> )	Compute spherical harmonics.

### scipy.special.lpmv

`scipy.special.lpmv` (*m*, *v*, *x*) = `<ufunc 'lpmv'>`  
 Associated Legendre function of integer order and real degree.

Defined as

$$P_v^m = (-1)^m (1 - x^2)^{m/2} \frac{d^m}{dx^m} P_v(x)$$

where

$$P_v = \sum_{k=0}^{\infty} \frac{(-v)_k (v+1)_k}{(k!)^2} \left(\frac{1-x}{2}\right)^k$$

is the Legendre function of the first kind. Here  $(\cdot)_k$  is the Pochhammer symbol; see [poch](#).

#### Parameters

- m** [array\_like] Order (int or float). If passed a float not equal to an integer the function returns NaN.
- v** [array\_like] Degree (float).
- x** [array\_like] Argument (float). Must have  $|x| \leq 1$ .

#### Returns

- pmv** [ndarray] Value of the associated Legendre function.

See also:

#### `lpmn`

Compute the associated Legendre function for all orders  $0, \dots, m$  and degrees  $0, \dots, n$ .

**clpmn**

Compute the associated Legendre function at complex arguments.

**Notes**

Note that this implementation includes the Condon-Shortley phase.

**References**

[1]

**scipy.special.sph\_harm**

`scipy.special.sph_harm(m, n, theta, phi)` = <ufunc 'sph\_harm'>

Compute spherical harmonics.

The spherical harmonics are defined as

$$Y_n^m(\theta, \phi) = \sqrt{\frac{2n+1}{4\pi} \frac{(n-m)!}{(n+m)!}} e^{im\theta} P_n^m(\cos(\phi))$$

where  $P_n^m$  are the associated Legendre functions; see [lpmv](#).

**Parameters**

- m** [array\_like] Order of the harmonic (int); must have  $|m| \leq n$ .
- n** [array\_like] Degree of the harmonic (int); must have  $n \geq 0$ . This is often denoted by  $l$  (lower case L) in descriptions of spherical harmonics.
- theta** [array\_like] Azimuthal (longitudinal) coordinate; must be in  $[0, 2\pi]$ .
- phi** [array\_like] Polar (colatitudinal) coordinate; must be in  $[0, \pi]$ .

**Returns**

- y\_mn** [complex float] The harmonic  $Y_n^m$  sampled at `theta` and `phi`.

**Notes**

There are different conventions for the meanings of the input arguments `theta` and `phi`. In SciPy `theta` is the azimuthal angle and `phi` is the polar angle. It is common to see the opposite convention, that is, `theta` as the polar angle and `phi` as the azimuthal angle.

Note that SciPy's spherical harmonics include the Condon-Shortley phase [2] because it is part of [lpmv](#).

With SciPy's conventions, the first several spherical harmonics are

$$\begin{aligned} Y_0^0(\theta, \phi) &= \frac{1}{2} \sqrt{\frac{1}{\pi}} \\ Y_1^{-1}(\theta, \phi) &= \frac{1}{2} \sqrt{\frac{3}{2\pi}} e^{-i\theta} \sin(\phi) \\ Y_1^0(\theta, \phi) &= \frac{1}{2} \sqrt{\frac{3}{\pi}} \cos(\phi) \\ Y_1^1(\theta, \phi) &= -\frac{1}{2} \sqrt{\frac{3}{2\pi}} e^{i\theta} \sin(\phi). \end{aligned}$$

## References

[1], [2]

These are not universal functions:

<code>lqn(n, z)</code>	Legendre function of the second kind.
<code>lpmn(m, n, z)</code>	Sequence of associated Legendre functions of the first kind.
<code>lqmn(m, n, z)</code>	Sequence of associated Legendre functions of the second kind.

## scipy.special.clpmn

`scipy.special.clpmn(m, n, z, type=3)`

Associated Legendre function of the first kind for complex arguments.

Computes the associated Legendre function of the first kind of order  $m$  and degree  $n$ ,  $P_{mn}(z) = P_n^m(z)$ , and its derivative,  $P_{mn}'(z)$ . Returns two arrays of size  $(m+1, n+1)$  containing  $P_{mn}(z)$  and  $P_{mn}'(z)$  for all orders from  $0 \dots m$  and degrees from  $0 \dots n$ .

### Parameters

- m** [int]  $|m| \leq n$ ; the order of the Legendre function.
- n** [int] where  $n \geq 0$ ; the degree of the Legendre function. Often called  $l$  (lower case L) in descriptions of the associated Legendre function
- z** [float or complex] Input value.
- type** [int, optional] takes values 2 or 3 2: cut on the real axis  $|x| > 1$  3: cut on the real axis  $-1 < x < 1$  (default)

### Returns

- Pmn\_z** [(m+1, n+1) array] Values for all orders  $0 \dots m$  and degrees  $0 \dots n$
- Pmn\_d\_z** [(m+1, n+1) array] Derivatives for all orders  $0 \dots m$  and degrees  $0 \dots n$

See also:

[lpmn](#)

associated Legendre functions of the first kind for real  $z$

## Notes

By default, i.e. for `type=3`, phase conventions are chosen according to [1] such that the function is analytic. The cut lies on the interval  $(-1, 1)$ . Approaching the cut from above or below in general yields a phase factor with respect to Ferrer's function of the first kind (cf. [lpmn](#)).

For `type=2` a cut at  $|x| > 1$  is chosen. Approaching the real values on the interval  $(-1, 1)$  in the complex plane yields Ferrer's function of the first kind.

## References

[1], [2]

**scipy.special.lpn**`scipy.special.lpn` ( $n, z$ )

Legendre function of the first kind.

Compute sequence of Legendre functions of the first kind (polynomials),  $P_n(z)$  and derivatives for all degrees from 0 to  $n$  (inclusive).

See also `special.legendre` for polynomial class.

**References**

[1]

**scipy.special.lqn**`scipy.special.lqn` ( $n, z$ )

Legendre function of the second kind.

Compute sequence of Legendre functions of the second kind,  $Q_n(z)$  and derivatives for all degrees from 0 to  $n$  (inclusive).

**References**

[1]

**scipy.special.lpmn**`scipy.special.lpmn` ( $m, n, z$ )

Sequence of associated Legendre functions of the first kind.

Computes the associated Legendre function of the first kind of order  $m$  and degree  $n$ ,  $P_{mn}(z) = P_n^m(z)$ , and its derivative,  $P_{mn}'(z)$ . Returns two arrays of size  $(m+1, n+1)$  containing  $P_{mn}(z)$  and  $P_{mn}'(z)$  for all orders from  $0 \dots m$  and degrees from  $0 \dots n$ .

This function takes a real argument  $z$ . For complex arguments  $z$  use `clpmn` instead.

**Parameters**

**m** [int]  $|m| \leq n$ ; the order of the Legendre function.  
**n** [int] where  $n \geq 0$ ; the degree of the Legendre function. Often called  $l$  (lower case L) in descriptions of the associated Legendre function  
**z** [float] Input value.

**Returns**

**Pmn\_z** [( $m+1, n+1$ ) array] Values for all orders  $0..m$  and degrees  $0..n$   
**Pmn\_d\_z** [( $m+1, n+1$ ) array] Derivatives for all orders  $0..m$  and degrees  $0..n$

See also:

**clpmn**

associated Legendre functions of the first kind for complex  $z$

**Notes**

In the interval  $(-1, 1)$ , Ferrer's function of the first kind is returned. The phase convention used for the intervals  $(1, \text{inf})$  and  $(-\text{inf}, -1)$  is such that the result is always real.

### scipy.special.lqmn

`scipy.special.lqmn(m, n, z)`

Sequence of associated Legendre functions of the second kind.

Computes the associated Legendre function of the second kind of order  $m$  and degree  $n$ ,  $Q_{mn}(z) = Q_n^m(z)$ , and its derivative,  $Q_{mn}'(z)$ . Returns two arrays of size  $(m+1, n+1)$  containing  $Q_{mn}(z)$  and  $Q_{mn}'(z)$  for all orders from  $0..m$  and degrees from  $0..n$ .

#### Parameters

**m** [int]  $|m| \leq n$ ; the order of the Legendre function.  
**n** [int] where  $n \geq 0$ ; the degree of the Legendre function. Often called  $l$  (lower case L) in descriptions of the associated Legendre function  
**z** [complex] Input value.

#### Returns

**Qmn\_z** [(m+1, n+1) array] Values for all orders  $0..m$  and degrees  $0..n$   
**Qmn\_d\_z** [(m+1, n+1) array] Derivatives for all orders  $0..m$  and degrees  $0..n$

### Ellipsoidal Harmonics

<code>ellip_harm(h2, k2, n, p, s[, signm, signn])</code>	Ellipsoidal harmonic functions $E^p_n(l)$
<code>ellip_harm_2(h2, k2, n, p, s)</code>	Ellipsoidal harmonic functions $F^p_n(l)$
<code>ellip_normal(h2, k2, n, p)</code>	Ellipsoidal harmonic normalization constants $\gamma^p_n$

### scipy.special.ellip\_harm

`scipy.special.ellip_harm(h2, k2, n, p, s, signm=1, signn=1)`

Ellipsoidal harmonic functions  $E^p_n(l)$

These are also known as Lamé functions of the first kind, and are solutions to the Lamé equation:

$$(s^2 - h^2)(s^2 - k^2)E''(s) + s(2s^2 - h^2 - k^2)E'(s) + (a - qs^2)E(s) = 0$$

where  $q = (n + 1)n$  and  $a$  is the eigenvalue (not returned) corresponding to the solutions.

#### Parameters

**h2** [float]  $h^2$   
**k2** [float]  $k^2$ ; should be larger than  $h^2$   
**n** [int] Degree  
**s** [float] Coordinate  
**p** [int] Order, can range between  $[1, 2n+1]$   
**signm** [{1, -1}, optional] Sign of prefactor of functions. Can be +/-1. See Notes.  
**signn** [{1, -1}, optional] Sign of prefactor of functions. Can be +/-1. See Notes.

**Returns****E** [float] the harmonic  $E_n^p(s)$ **See also:**`ellip_harm_2`, `ellip_normal`**Notes**

The geometric interpretation of the ellipsoidal functions is explained in [2], [3], [4]. The `signm` and `signn` arguments control the sign of prefactors for functions according to their type:

```
K : +1
L : signm
M : signn
N : signm*signn
```

New in version 0.15.0.

**References**

[1], [2], [3], [4]

**Examples**

```
>>> from scipy.special import ellip_harm
>>> w = ellip_harm(5, 8, 1, 1, 2.5)
>>> w
2.5
```

Check that the functions indeed are solutions to the Lamé equation:

```
>>> from scipy.interpolate import UnivariateSpline
>>> def eigenvalue(f, df, ddf):
... r = ((s**2 - h**2)*(s**2 - k**2)*ddf + s*(2*s**2 - h**2 -
... ↪ k**2)*df - n*(n+1)*s**2*f)/f
... return -r.mean(), r.std()
>>> s = np.linspace(0.1, 10, 200)
>>> k, h, n, p = 8.0, 2.2, 3, 2
>>> E = ellip_harm(h**2, k**2, n, p, s)
>>> E_spl = UnivariateSpline(s, E)
>>> a, a_err = eigenvalue(E_spl(s), E_spl(s,1), E_spl(s,2))
>>> a, a_err
(583.44366156701483, 6.4580890640310646e-11)
```

**scipy.special.ellip\_harm\_2**

`scipy.special.ellip_harm_2` ( $h2, k2, n, p, s$ )  
Ellipsoidal harmonic functions  $F_n^p(l)$

These are also known as Lamé functions of the second kind, and are solutions to the Lamé equation:

$$(s^2 - h^2)(s^2 - k^2)F''(s) + s(2s^2 - h^2 - k^2)F'(s) + (a - qs^2)F(s) = 0$$

where  $q = (n + 1)n$  and  $a$  is the eigenvalue (not returned) corresponding to the solutions.

#### Parameters

**h2** [float]  $h^{**2}$   
**k2** [float]  $k^{**2}$ ; should be larger than  $h^{**2}$   
**n** [int] Degree.  
**p** [int] Order, can range between  $[1, 2n+1]$ .  
**s** [float] Coordinate

#### Returns

**F** [float] The harmonic  $F_n^p(s)$

See also:

`ellip_harm`, `ellip_normal`

#### Notes

Lame functions of the second kind are related to the functions of the first kind:

$$F_n^p(s) = (2n + 1)E_n^p(s) \int_0^{1/s} \frac{du}{(E_n^p(1/u))^2 \sqrt{(1 - u^2k^2)(1 - u^2h^2)}}$$

New in version 0.15.0.

#### Examples

```
>>> from scipy.special import ellip_harm_2
>>> w = ellip_harm_2(5, 8, 2, 1, 10)
>>> w
0.00108056853382
```

### scipy.special.ellip\_normal

`scipy.special.ellip_normal(h2, k2, n, p)`

Ellipsoidal harmonic normalization constants  $\gamma_n^p$

The normalization constant is defined as

$$\gamma_n^p = 8 \int_0^h dx \int_h^k dy \frac{(y^2 - x^2)(E_n^p(y)E_n^p(x))^2}{\sqrt{((k^2 - y^2)(y^2 - h^2)(h^2 - x^2)(k^2 - x^2)}}$$

#### Parameters

**h2** [float]  $h^{**2}$   
**k2** [float]  $k^{**2}$ ; should be larger than  $h^{**2}$   
**n** [int] Degree.  
**p** [int] Order, can range between  $[1, 2n+1]$ .

#### Returns

**gamma** [float] The normalization constant  $\gamma_n^p$

See also:

`ellip_harm`, `ellip_harm_2`

## Notes

New in version 0.15.0.

## Examples

```
>>> from scipy.special import ellip_normal
>>> w = ellip_normal(5, 8, 3, 7)
>>> w
1723.38796997
```

## Orthogonal polynomials

The following functions evaluate values of orthogonal polynomials:

<code>assoc_laguerre(x, n[, k])</code>	Compute the generalized (associated) Laguerre polynomial of degree n and order k.
<code>eval_legendre(n, x[, out])</code>	Evaluate Legendre polynomial at a point.
<code>eval_chebyt(n, x[, out])</code>	Evaluate Chebyshev polynomial of the first kind at a point.
<code>eval_chebyu(n, x[, out])</code>	Evaluate Chebyshev polynomial of the second kind at a point.
<code>eval_chebyc(n, x[, out])</code>	Evaluate Chebyshev polynomial of the first kind on [-2, 2] at a point.
<code>eval_chebys(n, x[, out])</code>	Evaluate Chebyshev polynomial of the second kind on [-2, 2] at a point.
<code>eval_jacobi(n, alpha, beta, x[, out])</code>	Evaluate Jacobi polynomial at a point.
<code>eval_laguerre(n, x[, out])</code>	Evaluate Laguerre polynomial at a point.
<code>eval_genlaguerre(n, alpha, x[, out])</code>	Evaluate generalized Laguerre polynomial at a point.
<code>eval_hermite(n, x[, out])</code>	Evaluate physicist's Hermite polynomial at a point.
<code>eval_hermitenorm(n, x[, out])</code>	Evaluate probabilist's (normalized) Hermite polynomial at a point.
<code>eval_gegenbauer(n, alpha, x[, out])</code>	Evaluate Gegenbauer polynomial at a point.
<code>eval_sh_legendre(n, x[, out])</code>	Evaluate shifted Legendre polynomial at a point.
<code>eval_sh_chebyt(n, x[, out])</code>	Evaluate shifted Chebyshev polynomial of the first kind at a point.
<code>eval_sh_chebyu(n, x[, out])</code>	Evaluate shifted Chebyshev polynomial of the second kind at a point.
<code>eval_sh_jacobi(n, p, q, x[, out])</code>	Evaluate shifted Jacobi polynomial at a point.

### scipy.special.assoc\_laguerre

`scipy.special.assoc_laguerre(x, n, k=0.0)`

Compute the generalized (associated) Laguerre polynomial of degree n and order k.

The polynomial  $L_n^{(k)}(x)$  is orthogonal over  $[0, \infty)$ , with weighting function  $\exp(-x) * x^{**k}$  with  $k > -1$ .

## Notes

`assoc_laguerre` is a simple wrapper around `eval_genlaguerre`, with reversed argument order (`x, n, k=0.0`) --> (`n, k, x`).

**scipy.special.eval\_legendre**

`scipy.special.eval_legendre` (*n*, *x*, *out=None*) = <ufunc 'eval\_legendre'>  
Evaluate Legendre polynomial at a point.

The Legendre polynomials can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$P_n(x) = {}_2F_1(-n, n + 1; 1; (1 - x)/2).$$

When *n* is an integer the result is a polynomial of degree *n*.

**Parameters**

- n** [array\_like] Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.
- x** [array\_like] Points at which to evaluate the Legendre polynomial

**Returns**

- P** [ndarray] Values of the Legendre polynomial

**See also:**

**roots\_legendre**

roots and quadrature weights of Legendre polynomials

**legendre**

Legendre polynomial object

**hyp2f1**

Gauss hypergeometric function

**numpy.polynomial.legendre.Legendre**

Legendre series

**scipy.special.eval\_chebyt**

`scipy.special.eval_chebyt` (*n*, *x*, *out=None*) = <ufunc 'eval\_chebyt'>  
Evaluate Chebyshev polynomial of the first kind at a point.

The Chebyshev polynomials of the first kind can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$T_n(x) = {}_2F_1(n, -n; 1/2; (1 - x)/2).$$

When *n* is an integer the result is a polynomial of degree *n*.

**Parameters**

- n** [array\_like] Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.
- x** [array\_like] Points at which to evaluate the Chebyshev polynomial

**Returns**

- T** [ndarray] Values of the Chebyshev polynomial

**See also:**

**roots\_chebyt**

roots and quadrature weights of Chebyshev polynomials of the first kind

**chebyu**

Chebyshev polynomial object

**eval\_chebyu**

evaluate Chebyshev polynomials of the second kind

**hyp2f1**

Gauss hypergeometric function

**numpy.polynomial.chebyshev.Chebyshev**

Chebyshev series

**Notes**

This routine is numerically stable for  $x$  in  $[-1, 1]$  at least up to order 10000.

**scipy.special.eval\_chebyu**

`scipy.special.eval_chebyu(n, x, out=None) = <ufunc 'eval_chebyu'>`

Evaluate Chebyshev polynomial of the second kind at a point.

The Chebyshev polynomials of the second kind can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$U_n(x) = (n+1) {}_2F_1(-n, n+2; 3/2; (1-x)/2).$$

When  $n$  is an integer the result is a polynomial of degree  $n$ .

**Parameters**

- n** [array\_like] Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.
- x** [array\_like] Points at which to evaluate the Chebyshev polynomial

**Returns**

- U** [ndarray] Values of the Chebyshev polynomial

**See also:****roots\_chebyu**

roots and quadrature weights of Chebyshev polynomials of the second kind

**chebyu**

Chebyshev polynomial object

**eval\_chebyt**

evaluate Chebyshev polynomials of the first kind

**hyp2f1**

Gauss hypergeometric function

**scipy.special.eval\_chebyc**

`scipy.special.eval_chebyc(n, x, out=None) = <ufunc 'eval_chebyc'>`  
Evaluate Chebyshev polynomial of the first kind on  $[-2, 2]$  at a point.

These polynomials are defined as

$$S_n(x) = T_n(x/2)$$

where  $T_n$  is a Chebyshev polynomial of the first kind.

**Parameters**

- n** [array\_like] Degree of the polynomial. If not an integer, the result is determined via the relation to `eval_chebyt`.
- x** [array\_like] Points at which to evaluate the Chebyshev polynomial

**Returns**

- C** [ndarray] Values of the Chebyshev polynomial

**See also:****roots\_chebyc**

roots and quadrature weights of Chebyshev polynomials of the first kind on  $[-2, 2]$

**chebyc**

Chebyshev polynomial object

**numpy.polynomial.chebyshev.Chebyshev**

**eval\_chebyt**

evaluate Chebyshev polynomials of the first kind

**scipy.special.eval\_chebys**

`scipy.special.eval_chebys(n, x, out=None) = <ufunc 'eval_chebys'>`  
Evaluate Chebyshev polynomial of the second kind on  $[-2, 2]$  at a point.

These polynomials are defined as

$$S_n(x) = U_n(x/2)$$

where  $U_n$  is a Chebyshev polynomial of the second kind.

**Parameters**

- n** [array\_like] Degree of the polynomial. If not an integer, the result is determined via the relation to `eval_chebyu`.
- x** [array\_like] Points at which to evaluate the Chebyshev polynomial

**Returns**

- S** [ndarray] Values of the Chebyshev polynomial

**See also:****roots\_chebys**

roots and quadrature weights of Chebyshev polynomials of the second kind on  $[-2, 2]$

**chebys**

Chebyshev polynomial object

**eval\_chebyu**

evaluate Chebyshev polynomials of the second kind

**scipy.special.eval\_jacobi**

`scipy.special.eval_jacobi(n, alpha, beta, x, out=None)` = <ufunc 'eval\_jacobi'>  
Evaluate Jacobi polynomial at a point.

The Jacobi polynomials can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$P_n^{(\alpha, \beta)}(x) = \frac{(\alpha + 1)_n}{\Gamma(n + 1)} {}_2F_1(-n, 1 + \alpha + \beta + n; \alpha + 1; (1 - z)/2)$$

where  $(\cdot)_n$  is the Pochhammer symbol; see *poch*. When  $n$  is an integer the result is a polynomial of degree  $n$ .

**Parameters**

- n** [array\_like] Degree of the polynomial. If not an integer the result is determined via the relation to the Gauss hypergeometric function.
- alpha** [array\_like] Parameter
- beta** [array\_like] Parameter
- x** [array\_like] Points at which to evaluate the polynomial

**Returns**

- P** [ndarray] Values of the Jacobi polynomial

See also:

**roots\_jacobi**

**jacobi**

Jacobi polynomial object

**hyp2f1**

Gauss hypergeometric function

**scipy.special.eval\_laguerre**

`scipy.special.eval_laguerre(n, x, out=None)` = <ufunc 'eval\_laguerre'>  
Evaluate Laguerre polynomial at a point.

The Laguerre polynomials can be defined via the confluent hypergeometric function  ${}_1F_1$  as

$$L_n(x) = {}_1F_1(-n, 1, x).$$

When  $n$  is an integer the result is a polynomial of degree  $n$ .

**Parameters**

- n** [array\_like] Degree of the polynomial. If not an integer the result is determined via the relation to the confluent hypergeometric function.
- x** [array\_like] Points at which to evaluate the Laguerre polynomial

**Returns**

**L** [ndarray] Values of the Laguerre polynomial

**See also:**

[roots\\_laguerre](#)

roots and quadrature weights of Laguerre polynomials

[laguerre](#)

Laguerre polynomial object

[numpy.polynomial.laguerre.Laguerre](#)

Laguerre series

[eval\\_genlaguerre](#)

evaluate generalized Laguerre polynomials

### **scipy.special.eval\_genlaguerre**

`scipy.special.eval_genlaguerre(n, alpha, x, out=None) = <ufunc 'eval_genlaguerre'>`

Evaluate generalized Laguerre polynomial at a point.

The generalized Laguerre polynomials can be defined via the confluent hypergeometric function  ${}_1F_1$  as

$$L_n^{(\alpha)}(x) = \binom{n+\alpha}{n} {}_1F_1(-n, \alpha+1, x).$$

When  $n$  is an integer the result is a polynomial of degree  $n$ . The Laguerre polynomials are the special case where  $\alpha = 0$ .

#### **Parameters**

**n** [array\_like] Degree of the polynomial. If not an integer the result is determined via the relation to the confluent hypergeometric function.

**alpha** [array\_like] Parameter; must have `alpha > -1`

**x** [array\_like] Points at which to evaluate the generalized Laguerre polynomial

#### **Returns**

**L** [ndarray] Values of the generalized Laguerre polynomial

**See also:**

**scipy.special.eval\_hermite**

`scipy.special.eval_hermite` (*n*, *x*, *out=None*) = <ufunc 'eval\_hermite'>  
 Evaluate physicist's Hermite polynomial at a point.

Defined by

$$H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2};$$

$H_n$  is a polynomial of degree  $n$ .

**Parameters**

**n** [array\_like] Degree of the polynomial  
**x** [array\_like] Points at which to evaluate the Hermite polynomial

**Returns**

**H** [ndarray] Values of the Hermite polynomial

**See also:**

**roots\_hermite**

roots and quadrature weights of physicist's Hermite polynomials

**hermite**

physicist's Hermite polynomial object

**numpy.polynomial.hermite.Hermite**

Physicist's Hermite series

**eval\_hermitenorm**

evaluate Probabilist's Hermite polynomials

**scipy.special.eval\_hermitenorm**

`scipy.special.eval_hermitenorm` (*n*, *x*, *out=None*) = <ufunc 'eval\_hermitenorm'>  
 Evaluate probabilist's (normalized) Hermite polynomial at a point.

Defined by

$$He_n(x) = (-1)^n e^{x^2/2} \frac{d^n}{dx^n} e^{-x^2/2};$$

$He_n$  is a polynomial of degree  $n$ .

**Parameters**

**n** [array\_like] Degree of the polynomial  
**x** [array\_like] Points at which to evaluate the Hermite polynomial

**Returns**

**He** [ndarray] Values of the Hermite polynomial

**See also:**

**roots\_hermitenorm**

roots and quadrature weights of probabilist's Hermite polynomials

**hermitenorm**

probabilist's Hermite polynomial object

`numpy.polynomial.hermite_e.HermiteE`

Probabilist's Hermite series

**eval\_hermite**

evaluate physicist's Hermite polynomials

**scipy.special.eval\_gegenbauer**

`scipy.special.eval_gegenbauer(n, alpha, x, out=None) = <ufunc 'eval_gegenbauer'>`

Evaluate Gegenbauer polynomial at a point.

The Gegenbauer polynomials can be defined via the Gauss hypergeometric function  ${}_2F_1$  as

$$C_n^{(\alpha)} = \frac{(2\alpha)_n}{\Gamma(n+1)} {}_2F_1(-n, 2\alpha+n; \alpha+1/2; (1-z)/2).$$

When  $n$  is an integer the result is a polynomial of degree  $n$ .

**Parameters**

- n** [array\_like] Degree of the polynomial. If not an integer, the result is determined via the relation to the Gauss hypergeometric function.
- alpha** [array\_like] Parameter
- x** [array\_like] Points at which to evaluate the Gegenbauer polynomial

**Returns**

- C** [ndarray] Values of the Gegenbauer polynomial

See also:

**roots\_gegenbauer**

roots and quadrature weights of Gegenbauer polynomials

**gegenbauer**

Gegenbauer polynomial object

**hyp2f1**

Gauss hypergeometric function

**scipy.special.eval\_sh\_legendre**

`scipy.special.eval_sh_legendre(n, x, out=None) = <ufunc 'eval_sh_legendre'>`

Evaluate shifted Legendre polynomial at a point.

These polynomials are defined as

$$P_n^*(x) = P_n(2x - 1)$$

where  $P_n$  is a Legendre polynomial.

**Parameters**

- n** [array\_like] Degree of the polynomial. If not an integer, the value is determined via the relation to `eval_legendre`.
- x** [array\_like] Points at which to evaluate the shifted Legendre polynomial

**Returns**

**P** [ndarray] Values of the shifted Legendre polynomial

**See also:****roots\_sh\_legendre**

roots and quadrature weights of shifted Legendre polynomials

**sh\_legendre**

shifted Legendre polynomial object

**eval\_legendre**

evaluate Legendre polynomials

**numpy.polynomial.legendre.Legendre**

Legendre series

**scipy.special.eval\_sh\_chebyt**

`scipy.special.eval_sh_chebyt(n, x, out=None) = <ufunc 'eval_sh_chebyt'>`

Evaluate shifted Chebyshev polynomial of the first kind at a point.

These polynomials are defined as

$$T_n^*(x) = T_n(2x - 1)$$

where  $T_n$  is a Chebyshev polynomial of the first kind.

**Parameters**

**n** [array\_like] Degree of the polynomial. If not an integer, the result is determined via the relation to `eval_chebyt`.

**x** [array\_like] Points at which to evaluate the shifted Chebyshev polynomial

**Returns**

**T** [ndarray] Values of the shifted Chebyshev polynomial

**See also:****roots\_sh\_chebyt**

roots and quadrature weights of shifted Chebyshev polynomials of the first kind

**sh\_chebyt**

shifted Chebyshev polynomial object

**eval\_chebyt**

evaluate Chebyshev polynomials of the first kind

**numpy.polynomial.chebyshev.Chebyshev**

Chebyshev series

### scipy.special.eval\_sh\_chebyu

`scipy.special.eval_sh_chebyu(n, x, out=None) = <ufunc 'eval_sh_chebyu'>`  
 Evaluate shifted Chebyshev polynomial of the second kind at a point.

These polynomials are defined as

$$U_n^*(x) = U_n(2x - 1)$$

where  $U_n$  is a Chebyshev polynomial of the first kind.

#### Parameters

- n** [array\_like] Degree of the polynomial. If not an integer, the result is determined via the relation to `eval_chebyu`.
- x** [array\_like] Points at which to evaluate the shifted Chebyshev polynomial

#### Returns

- U** [ndarray] Values of the shifted Chebyshev polynomial

See also:

#### [roots\\_sh\\_chebyu](#)

roots and quadrature weights of shifted Chebyshev polynomials of the second kind

#### [sh\\_chebyu](#)

shifted Chebyshev polynomial object

#### [eval\\_chebyu](#)

evaluate Chebyshev polynomials of the second kind

### scipy.special.eval\_sh\_jacobi

`scipy.special.eval_sh_jacobi(n, p, q, x, out=None) = <ufunc 'eval_sh_jacobi'>`  
 Evaluate shifted Jacobi polynomial at a point.

Defined by

$$G_n^{(p,q)}(x) = \binom{2n+p-1}{n}^{-1} P_n^{(p-q, q-1)}(2x-1),$$

where  $P_n^{(\cdot, \cdot)}$  is the n-th Jacobi polynomial.

#### Parameters

- n** [int] Degree of the polynomial. If not an integer, the result is determined via the relation to `binom` and `eval_jacobi`.
- p** [float] Parameter
- q** [float] Parameter

#### Returns

- G** [ndarray] Values of the shifted Jacobi polynomial.

See also:

#### [roots\\_sh\\_jacobi](#)

roots and quadrature weights of shifted Jacobi polynomials

**sh\_jacobi**

shifted Jacobi polynomial object

**eval\_jacobi**

evaluate Jacobi polynomials

The following functions compute roots and quadrature weights for orthogonal polynomials:

<code>roots_legendre(n[, mu])</code>	Gauss-Legendre quadrature.
<code>roots_chebyt(n[, mu])</code>	Gauss-Chebyshev (first kind) quadrature.
<code>roots_chebyu(n[, mu])</code>	Gauss-Chebyshev (second kind) quadrature.
<code>roots_chebyc(n[, mu])</code>	Gauss-Chebyshev (first kind) quadrature.
<code>roots_chebys(n[, mu])</code>	Gauss-Chebyshev (second kind) quadrature.
<code>roots_jacobi(n, alpha, beta[, mu])</code>	Gauss-Jacobi quadrature.
<code>roots_laguerre(n[, mu])</code>	Gauss-Laguerre quadrature.
<code>roots_genlaguerre(n, alpha[, mu])</code>	Gauss-generalized Laguerre quadrature.
<code>roots_hermite(n[, mu])</code>	Gauss-Hermite (physicst's) quadrature.
<code>roots_hermitenorm(n[, mu])</code>	Gauss-Hermite (statistician's) quadrature.
<code>roots_gegenbauer(n, alpha[, mu])</code>	Gauss-Gegenbauer quadrature.
<code>roots_sh_legendre(n[, mu])</code>	Gauss-Legendre (shifted) quadrature.
<code>roots_sh_chebyt(n[, mu])</code>	Gauss-Chebyshev (first kind, shifted) quadrature.
<code>roots_sh_chebyu(n[, mu])</code>	Gauss-Chebyshev (second kind, shifted) quadrature.
<code>roots_sh_jacobi(n, p1, q1[, mu])</code>	Gauss-Jacobi (shifted) quadrature.

**scipy.special.roots\_legendre**

`scipy.special.roots_legendre(n, mu=False)`

Gauss-Legendre quadrature.

Computes the sample points and weights for Gauss-Legendre quadrature. The sample points are the roots of the  $n$ -th degree Legendre polynomial  $P_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-1, 1]$  with weight function  $f(x) = 1.0$ .

**Parameters**

**n** [int] quadrature order  
**mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

**x** [ndarray] Sample points  
**w** [ndarray] Weights  
**mu** [float] Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`, `numpy.polynomial.legendre.leggauss`

**scipy.special.roots\_chebyt**

`scipy.special.roots_chebyt(n, mu=False)`

Gauss-Chebyshev (first kind) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the  $n$ -th degree Chebyshev polynomial of the first kind,  $T_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-1, 1]$  with weight function  $f(x) = 1/\sqrt{1 - x^2}$ .

**Parameters**

**n** [int] quadrature order  
**mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

**x** [ndarray] Sample points  
**w** [ndarray] Weights  
**mu** [float] Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`, `numpy.polynomial.chebyshev.chebgauss`

**scipy.special.roots\_chebyu**

`scipy.special.roots_chebyu` (*n*, *mu=False*)  
 Gauss-Chebyshev (second kind) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the *n*-th degree Chebyshev polynomial of the second kind,  $U_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-1, 1]$  with weight function  $f(x) = \sqrt{1 - x^2}$ .

**Parameters**

**n** [int] quadrature order  
**mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

**x** [ndarray] Sample points  
**w** [ndarray] Weights  
**mu** [float] Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

**scipy.special.roots\_chebyc**

`scipy.special.roots_chebyc` (*n*, *mu=False*)  
 Gauss-Chebyshev (first kind) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the *n*-th degree Chebyshev polynomial of the first kind,  $C_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-2, 2]$  with weight function  $f(x) = 1/\sqrt{1 - (x/2)^2}$ .

**Parameters**

**n** [int] quadrature order  
**mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

**x** [ndarray] Sample points  
**w** [ndarray] Weights  
**mu** [float] Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

**scipy.special.roots\_chebys**

`scipy.special.roots_chebys` (*n*, *mu=False*)

Gauss-Chebyshev (second kind) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the *n*-th degree Chebyshev polynomial of the second kind,  $S_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-2, 2]$  with weight function  $f(x) = \sqrt{1 - (x/2)^2}$ .

**Parameters**

**n** [int] quadrature order  
**mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

**x** [ndarray] Sample points  
**w** [ndarray] Weights  
**mu** [float] Sum of the weights

See also:

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

**scipy.special.roots\_jacobi**

`scipy.special.roots_jacobi` (*n*, *alpha*, *beta*, *mu=False*)

Gauss-Jacobi quadrature.

Computes the sample points and weights for Gauss-Jacobi quadrature. The sample points are the roots of the *n*-th degree Jacobi polynomial,  $P_n^{\alpha,\beta}(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-1, 1]$  with weight function  $f(x) = (1 - x)^\alpha(1 + x)^\beta$ .

**Parameters**

**n** [int] quadrature order  
**alpha** [float] alpha must be  $> -1$   
**beta** [float] beta must be  $> -1$   
**mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

**x** [ndarray] Sample points  
**w** [ndarray] Weights  
**mu** [float] Sum of the weights

See also:

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

**scipy.special.roots\_laguerre**

`scipy.special.roots_laguerre` (*n*, *mu=False*)

Gauss-Laguerre quadrature.

Computes the sample points and weights for Gauss-Laguerre quadrature. The sample points are the roots of the *n*-th degree Laguerre polynomial,  $L_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[0, \infty]$  with weight function  $f(x) = e^{-x}$ .

**Parameters**

**n** [int] quadrature order  
**mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

**x** [ndarray] Sample points  
**w** [ndarray] Weights  
**mu** [float] Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`, `numpy.polynomial.laguerre.laggauss`

### **scipy.special.roots\_genlaguerre**

`scipy.special.roots_genlaguerre` (*n*, *alpha*, *mu=False*)

Gauss-generalized Laguerre quadrature.

Computes the sample points and weights for Gauss-generalized Laguerre quadrature. The sample points are the roots of the *n*-th degree generalized Laguerre polynomial,  $L_n^\alpha(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[0, \infty]$  with weight function  $f(x) = x^\alpha e^{-x}$ .

**Parameters**

**n** [int] quadrature order  
**alpha** [float] alpha must be  $> -1$   
**mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

**x** [ndarray] Sample points  
**w** [ndarray] Weights  
**mu** [float] Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

### **scipy.special.roots\_hermite**

`scipy.special.roots_hermite` (*n*, *mu=False*)

Gauss-Hermite (physicst's) quadrature.

Computes the sample points and weights for Gauss-Hermite quadrature. The sample points are the roots of the *n*-th degree Hermite polynomial,  $H_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-\infty, \infty]$  with weight function  $f(x) = e^{-x^2}$ .

**Parameters**

**n** [int] quadrature order  
**mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

**x** [ndarray] Sample points  
**w** [ndarray] Weights  
**mu** [float] Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`, `numpy.polynomial.hermite.hermgauss`, `roots_hermitenorm`

## Notes

For small  $n$  up to 150 a modified version of the Golub-Welsch algorithm is used. Nodes are computed from the eigenvalue problem and improved by one step of a Newton iteration. The weights are computed from the well-known analytical formula.

For  $n$  larger than 150 an optimal asymptotic algorithm is applied which computes nodes and weights in a numerically stable manner. The algorithm has linear runtime making computation for very large  $n$  (several thousand or more) feasible.

### scipy.special.roots\_hermitenorm

`scipy.special.roots_hermitenorm` ( $n$ ,  $mu=False$ )

Gauss-Hermite (statistician's) quadrature.

Computes the sample points and weights for Gauss-Hermite quadrature. The sample points are the roots of the  $n$ -th degree Hermite polynomial,  $He_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-\infty, \infty]$  with weight function  $f(x) = e^{-x^2/2}$ .

#### Parameters

**n** [int] quadrature order  
**mu** [bool, optional] If True, return the sum of the weights, optional.

#### Returns

**x** [ndarray] Sample points  
**w** [ndarray] Weights  
**mu** [float] Sum of the weights

#### See also:

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`, `numpy.polynomial.hermite_e.hermegauss`

### scipy.special.roots\_gegenbauer

`scipy.special.roots_gegenbauer` ( $n$ ,  $alpha$ ,  $mu=False$ )

Gauss-Gegenbauer quadrature.

Computes the sample points and weights for Gauss-Gegenbauer quadrature. The sample points are the roots of the  $n$ -th degree Gegenbauer polynomial,  $C_n^\alpha(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[-1, 1]$  with weight function  $f(x) = (1 - x^2)^{\alpha-1/2}$ .

#### Parameters

**n** [int] quadrature order  
**alpha** [float] alpha must be > -0.5  
**mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

**x** [ndarray] Sample points  
**w** [ndarray] Weights  
**mu** [float] Sum of the weights

**See also:**

*scipy.integrate.quadrature, scipy.integrate.fixed\_quad*

**scipy.special.roots\_sh\_legendre**

`scipy.special.roots_sh_legendre` (*n, mu=False*)  
 Gauss-Legendre (shifted) quadrature.

Computes the sample points and weights for Gauss-Legendre quadrature. The sample points are the roots of the  $n$ -th degree shifted Legendre polynomial  $P_n^*(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[0, 1]$  with weight function  $f(x) = 1.0$ .

**Parameters**

**n** [int] quadrature order  
**mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

**x** [ndarray] Sample points  
**w** [ndarray] Weights  
**mu** [float] Sum of the weights

**See also:**

*scipy.integrate.quadrature, scipy.integrate.fixed\_quad*

**scipy.special.roots\_sh\_chebyt**

`scipy.special.roots_sh_chebyt` (*n, mu=False*)  
 Gauss-Chebyshev (first kind, shifted) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the  $n$ -th degree shifted Chebyshev polynomial of the first kind,  $T_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[0, 1]$  with weight function  $f(x) = 1/\sqrt{x - x^2}$ .

**Parameters**

**n** [int] quadrature order  
**mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

**x** [ndarray] Sample points  
**w** [ndarray] Weights  
**mu** [float] Sum of the weights

**See also:**

*scipy.integrate.quadrature, scipy.integrate.fixed\_quad*

**scipy.special.roots\_sh\_chebyu**

`scipy.special.roots_sh_chebyu` (*n*, *mu=False*)

Gauss-Chebyshev (second kind, shifted) quadrature.

Computes the sample points and weights for Gauss-Chebyshev quadrature. The sample points are the roots of the *n*-th degree shifted Chebyshev polynomial of the second kind,  $U_n(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[0, 1]$  with weight function  $f(x) = \sqrt{x - x^2}$ .

**Parameters**

**n** [int] quadrature order  
**mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

**x** [ndarray] Sample points  
**w** [ndarray] Weights  
**mu** [float] Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

**scipy.special.roots\_sh\_jacobi**

`scipy.special.roots_sh_jacobi` (*n*, *p1*, *q1*, *mu=False*)

Gauss-Jacobi (shifted) quadrature.

Computes the sample points and weights for Gauss-Jacobi (shifted) quadrature. The sample points are the roots of the *n*-th degree shifted Jacobi polynomial,  $G_n^{p,q}(x)$ . These sample points and weights correctly integrate polynomials of degree  $2n - 1$  or less over the interval  $[0, 1]$  with weight function  $f(x) = (1 - x)^{p-q}x^{q-1}$

**Parameters**

**n** [int] quadrature order  
**p1** [float] (*p1* - *q1*) must be > -1  
**q1** [float] *q1* must be > 0  
**mu** [bool, optional] If True, return the sum of the weights, optional.

**Returns**

**x** [ndarray] Sample points  
**w** [ndarray] Weights  
**mu** [float] Sum of the weights

**See also:**

`scipy.integrate.quadrature`, `scipy.integrate.fixed_quad`

The functions below, in turn, return the polynomial coefficients in `orthopoly1d` objects, which function similarly as `numpy.poly1d`. The `orthopoly1d` class also has an attribute `weights` which returns the roots, weights, and total weights for the appropriate form of Gaussian quadrature. These are returned in an  $n \times 3$  array with roots in the first column, weights in the second column, and total weights in the final column. Note that `orthopoly1d` objects are converted to `poly1d` when doing arithmetic, and lose information of the original orthogonal polynomial.

<code>legendre</code> ( <i>n</i> [, <i>monic</i> ])	Legendre polynomial.

### scipy.special.legendre

`scipy.special.legendre` (*n*, *monic=False*)  
Legendre polynomial.

Defined to be the solution of

$$\frac{d}{dx} \left[ (1 - x^2) \frac{d}{dx} P_n(x) \right] + n(n + 1)P_n(x) = 0;$$

$P_n(x)$  is a polynomial of degree  $n$ .

#### Parameters

- n** [int] Degree of the polynomial.
- monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

#### Returns

- P** [orthopoly1d] Legendre polynomial.

### Notes

The polynomials  $P_n$  are orthogonal over  $[-1, 1]$  with weight function 1.

### Examples

Generate the 3rd-order Legendre polynomial  $1/2*(5x^3 + 0x^2 - 3x + 0)$ :

```
>>> from scipy.special import legendre
>>> legendre(3)
poly1d([2.5, 0. , -1.5, 0.])
```

### scipy.special.chebyt

`scipy.special.chebyt` (*n*, *monic=False*)  
Chebyshev polynomial of the first kind.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} T_n - x \frac{d}{dx} T_n + n^2 T_n = 0;$$

$T_n$  is a polynomial of degree  $n$ .

#### Parameters

**n** [int] Degree of the polynomial.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

**T** [orthopoly1d] Chebyshev polynomial of the first kind.

**See also:****chebyu**

Chebyshev polynomial of the second kind.

**Notes**

The polynomials  $T_n$  are orthogonal over  $[-1, 1]$  with weight function  $(1 - x^2)^{-1/2}$ .

**scipy.special.chebyu**

`scipy.special.chebyu` (*n*, *monic=False*)  
 Chebyshev polynomial of the second kind.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} U_n - 3x \frac{d}{dx} U_n + n(n + 2) U_n = 0;$$

$U_n$  is a polynomial of degree  $n$ .

**Parameters**

**n** [int] Degree of the polynomial.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

**U** [orthopoly1d] Chebyshev polynomial of the second kind.

**See also:****chebyt**

Chebyshev polynomial of the first kind.

**Notes**

The polynomials  $U_n$  are orthogonal over  $[-1, 1]$  with weight function  $(1 - x^2)^{1/2}$ .

**scipy.special.chebyc**

`scipy.special.chebyc` (*n*, *monic=False*)  
 Chebyshev polynomial of the first kind on  $[-2, 2]$ .

Defined as  $C_n(x) = 2T_n(x/2)$ , where  $T_n$  is the  $n$ th Chebychev polynomial of the first kind.

**Parameters**

**n** [int] Degree of the polynomial.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

**C** [orthopoly1d] Chebyshev polynomial of the first kind on  $[-2, 2]$ .

**See also:**

[chebyt](#)

Chebyshev polynomial of the first kind.

### Notes

The polynomials  $C_n(x)$  are orthogonal over  $[-2, 2]$  with weight function  $1/\sqrt{1 - (x/2)^2}$ .

### References

[1]

### scipy.special.chebys

`scipy.special.chebys` (*n*, *monic=False*)

Chebyshev polynomial of the second kind on  $[-2, 2]$ .

Defined as  $S_n(x) = U_n(x/2)$  where  $U_n$  is the *n*th Chebyshev polynomial of the second kind.

#### Parameters

**n** [int] Degree of the polynomial.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

#### Returns

**S** [orthopoly1d] Chebyshev polynomial of the second kind on  $[-2, 2]$ .

**See also:**

[chebyu](#)

Chebyshev polynomial of the second kind

### Notes

The polynomials  $S_n(x)$  are orthogonal over  $[-2, 2]$  with weight function  $\sqrt{1 - (x/2)^2}$ .

### References

[1]

### scipy.special.jacobi

`scipy.special.jacobi` (*n*, *alpha*, *beta*, *monic=False*)

Jacobi polynomial.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} P_n^{(\alpha, \beta)} + (\beta - \alpha - (\alpha + \beta + 2)x) \frac{d}{dx} P_n^{(\alpha, \beta)} + n(n + \alpha + \beta + 1) P_n^{(\alpha, \beta)} = 0$$

for  $\alpha, \beta > -1$ ;  $P_n^{(\alpha, \beta)}$  is a polynomial of degree *n*.

**Parameters**

<b>n</b>	[int] Degree of the polynomial.
<b>alpha</b>	[float] Parameter, must be greater than -1.
<b>beta</b>	[float] Parameter, must be greater than -1.
<b>monic</b>	[bool, optional] If <i>True</i> , scale the leading coefficient to be 1. Default is <i>False</i> .

**Returns**

<b>P</b>	[orthopoly1d] Jacobi polynomial.
----------	----------------------------------

**Notes**

For fixed  $\alpha, \beta$ , the polynomials  $P_n^{(\alpha, \beta)}$  are orthogonal over  $[-1, 1]$  with weight function  $(1-x)^\alpha(1+x)^\beta$ .

**scipy.special.laguerre**

`scipy.special.laguerre` (*n*, *monic=False*)

Laguerre polynomial.

Defined to be the solution of

$$x \frac{d^2}{dx^2} L_n + (1-x) \frac{d}{dx} L_n + n L_n = 0;$$

$L_n$  is a polynomial of degree  $n$ .

**Parameters**

<b>n</b>	[int] Degree of the polynomial.
<b>monic</b>	[bool, optional] If <i>True</i> , scale the leading coefficient to be 1. Default is <i>False</i> .

**Returns**

<b>L</b>	[orthopoly1d] Laguerre Polynomial.
----------	------------------------------------

**Notes**

The polynomials  $L_n$  are orthogonal over  $[0, \infty)$  with weight function  $e^{-x}$ .

**scipy.special.genlaguerre**

`scipy.special.genlaguerre` (*n*, *alpha*, *monic=False*)

Generalized (associated) Laguerre polynomial.

Defined to be the solution of

$$x \frac{d^2}{dx^2} L_n^{(\alpha)} + (\alpha + 1 - x) \frac{d}{dx} L_n^{(\alpha)} + n L_n^{(\alpha)} = 0,$$

where  $\alpha > -1$ ;  $L_n^{(\alpha)}$  is a polynomial of degree  $n$ .

**Parameters**

<b>n</b>	[int] Degree of the polynomial.
<b>alpha</b>	[float] Parameter, must be greater than -1.
<b>monic</b>	[bool, optional] If <i>True</i> , scale the leading coefficient to be 1. Default is <i>False</i> .

**Returns**

<b>L</b>	[orthopoly1d] Generalized Laguerre polynomial.
----------	------------------------------------------------

See also:

### laguerre

Laguerre polynomial.

### Notes

For fixed  $\alpha$ , the polynomials  $L_n^{(\alpha)}$  are orthogonal over  $[0, \infty)$  with weight function  $e^{-x}x^\alpha$ .

The Laguerre polynomials are the special case where  $\alpha = 0$ .

### scipy.special.hermite

`scipy.special.hermite` ( $n$ , *monic=False*)

Physicist's Hermite polynomial.

Defined by

$$H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2};$$

$H_n$  is a polynomial of degree  $n$ .

#### Parameters

- n** [int] Degree of the polynomial.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

#### Returns

- H** [orthopoly1d] Hermite polynomial.

### Notes

The polynomials  $H_n$  are orthogonal over  $(-\infty, \infty)$  with weight function  $e^{-x^2}$ .

### scipy.special.hermite norm

`scipy.special.hermite norm` ( $n$ , *monic=False*)

Normalized (probabilist's) Hermite polynomial.

Defined by

$$He_n(x) = (-1)^n e^{x^2/2} \frac{d^n}{dx^n} e^{-x^2/2};$$

$He_n$  is a polynomial of degree  $n$ .

#### Parameters

- n** [int] Degree of the polynomial.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

#### Returns

- He** [orthopoly1d] Hermite polynomial.

## Notes

The polynomials  $He_n$  are orthogonal over  $(-\infty, \infty)$  with weight function  $e^{-x^2/2}$ .

### scipy.special.gegenbauer

`scipy.special.gegenbauer` ( $n$ ,  $alpha$ ,  $monic=False$ )

Gegenbauer (ultraspherical) polynomial.

Defined to be the solution of

$$(1 - x^2) \frac{d^2}{dx^2} C_n^{(\alpha)} - (2\alpha + 1)x \frac{d}{dx} C_n^{(\alpha)} + n(n + 2\alpha) C_n^{(\alpha)} = 0$$

for  $\alpha > -1/2$ ;  $C_n^{(\alpha)}$  is a polynomial of degree  $n$ .

#### Parameters

- n** [int] Degree of the polynomial.
- monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

#### Returns

- C** [orthopoly1d] Gegenbauer polynomial.

## Notes

The polynomials  $C_n^{(\alpha)}$  are orthogonal over  $[-1, 1]$  with weight function  $(1 - x^2)^{(\alpha-1/2)}$ .

### scipy.special.sh\_legendre

`scipy.special.sh_legendre` ( $n$ ,  $monic=False$ )

Shifted Legendre polynomial.

Defined as  $P_n^*(x) = P_n(2x - 1)$  for  $P_n$  the  $n$ th Legendre polynomial.

#### Parameters

- n** [int] Degree of the polynomial.
- monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

#### Returns

- P** [orthopoly1d] Shifted Legendre polynomial.

## Notes

The polynomials  $P_n^*$  are orthogonal over  $[0, 1]$  with weight function 1.

### scipy.special.sh\_chebyt

`scipy.special.sh_chebyt` ( $n$ ,  $monic=False$ )

Shifted Chebyshev polynomial of the first kind.

Defined as  $T_n^*(x) = T_n(2x - 1)$  for  $T_n$  the  $n$ th Chebyshev polynomial of the first kind.

#### Parameters

- n** [int] Degree of the polynomial.
- monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

**T** [orthopoly1d] Shifted Chebyshev polynomial of the first kind.

**Notes**

The polynomials  $T_n^*$  are orthogonal over  $[0, 1]$  with weight function  $(x - x^2)^{-1/2}$ .

**scipy.special.sh\_chebyu**

`scipy.special.sh_chebyu` (*n*, *monic=False*)

Shifted Chebyshev polynomial of the second kind.

Defined as  $U_n^*(x) = U_n(2x - 1)$  for  $U_n$  the *n*th Chebyshev polynomial of the second kind.

**Parameters**

**n** [int] Degree of the polynomial.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

**U** [orthopoly1d] Shifted Chebyshev polynomial of the second kind.

**Notes**

The polynomials  $U_n^*$  are orthogonal over  $[0, 1]$  with weight function  $(x - x^2)^{1/2}$ .

**scipy.special.sh\_jacobi**

`scipy.special.sh_jacobi` (*n*, *p*, *q*, *monic=False*)

Shifted Jacobi polynomial.

Defined by

$$G_n^{(p,q)}(x) = \binom{2n+p-1}{n}^{-1} P_n^{(p-q, q-1)}(2x-1),$$

where  $P_n^{(\cdot, \cdot)}$  is the *n*th Jacobi polynomial.

**Parameters**

**n** [int] Degree of the polynomial.  
**p** [float] Parameter, must have  $p > q - 1$ .  
**q** [float] Parameter, must be greater than 0.  
**monic** [bool, optional] If *True*, scale the leading coefficient to be 1. Default is *False*.

**Returns**

**G** [orthopoly1d] Shifted Jacobi polynomial.

**Notes**

For fixed *p*, *q*, the polynomials  $G_n^{(p,q)}$  are orthogonal over  $[0, 1]$  with weight function  $(1 - x)^{p-q} x^{q-1}$ .

**Warning:** Computing values of high-order polynomials (around `order > 20`) using polynomial coefficients is numerically unstable. To evaluate polynomial values, the `eval_*` functions should be used instead.

## Hypergeometric Functions

<code>hyp2f1(a, b, c, z)</code>	Gauss hypergeometric function ${}_2F_1(a, b; c; z)$
<code>hyp1f1(a, b, x)</code>	Confluent hypergeometric function ${}_1F_1(a, b; x)$
<code>hyperu(a, b, x)</code>	Confluent hypergeometric function $U(a, b, x)$ of the second kind
<code>hyp0f1(v, x)</code>	Confluent hypergeometric limit function ${}_0F_1$ .
<code>hyp2f0(a, b, x, type)</code>	<code>hyp2f0</code> is deprecated! <code>hyp2f0</code> is deprecated in SciPy 1.2
<code>hyp1f2(a, b, c, x)</code>	<code>hyp1f2</code> is deprecated! <code>hyp1f2</code> is deprecated in SciPy 1.2
<code>hyp3f0(a, b, c, x)</code>	<code>hyp3f0</code> is deprecated! <code>hyp3f0</code> is deprecated in SciPy 1.2

### `scipy.special.hyp2f1`

`scipy.special.hyp2f1(a, b, c, z) = <ufunc 'hyp2f1'>`

Gauss hypergeometric function  ${}_2F_1(a, b; c; z)$

#### Parameters

**a, b, c** [array\_like] Arguments, should be real-valued.  
**z** [array\_like] Argument, real or complex.

#### Returns

**hyp2f1** [scalar or ndarray] The values of the gaussian hypergeometric function.

See also:

#### `hyp0f1`

confluent hypergeometric limit function.

#### `hyp1f1`

Kummer's (confluent hypergeometric) function.

#### Notes

This function is defined for  $|z| < 1$  as

$$\text{hyp2f1}(a, b, c, z) = \sum_{n=0}^{\infty} \frac{(a)_n (b)_n}{(c)_n} \frac{z^n}{n!},$$

and defined on the rest of the complex  $z$ -plane by analytic continuation. Here  $(\cdot)_n$  is the Pochhammer symbol; see *poch*. When  $n$  is an integer the result is a polynomial of degree  $n$ .

The implementation for complex values of  $z$  is described in [1].

#### References

Confluent hypergeometric function  $1F1(a, b; x)$

**scipy.special.hyperu**

`scipy.special.hyperu(a, b, x) = <ufunc 'hyperu'>`  
Confluent hypergeometric function  $U(a, b, x)$  of the second kind

**scipy.special.hyp0f1**

`scipy.special.hyp0f1(v, x) = <ufunc 'hyp0f1'>`  
Confluent hypergeometric limit function  $0F1$ .

**Parameters**

**v, z** [array\_like] Input values.

**Returns**

**hyp0f1** [ndarray] The confluent hypergeometric limit function.

**Notes**

This function is defined as:

$${}_0F_1(v, z) = \sum_{k=0}^{\infty} \frac{z^k}{(v)_k k!}.$$

It's also the limit as  $q \rightarrow \infty$  of  ${}_1F_1(q; v; z/q)$ , and satisfies the differential equation  $f''(z) + vf'(z) = f(z)$ .

**scipy.special.hyp2f0**

`scipy.special.hyp2f0(a, b, x, type)`  
*hyp2f0* is deprecated! *hyp2f0* is deprecated in SciPy 1.2

Hypergeometric function  $2F0$  in  $y$  and an error estimate

The parameter *type* determines a convergence factor and can be either 1 or 2.

**Returns**

**y** Value of the function  
**err** Error estimate

**scipy.special.hyp1f2**

`scipy.special.hyp1f2(a, b, c, x)`  
*hyp1f2* is deprecated! *hyp1f2* is deprecated in SciPy 1.2

Hypergeometric function  $1F2$  and error estimate

**Returns**

**y** Value of the function  
**err** Error estimate

**scipy.special.hyp3f0**

`scipy.special.hyp3f0(a, b, c, x)`

`hyp3f0` is deprecated! `hyp3f0` is deprecated in SciPy 1.2

Hypergeometric function 3F0 in  $y$  and an error estimate

**Returns**

**y** Value of the function  
**err** Error estimate

**Parabolic Cylinder Functions**

<code>pbdv(v, x)</code>	Parabolic cylinder function D
<code>pbvv(v, x)</code>	Parabolic cylinder function V
<code>pbwa(a, x)</code>	Parabolic cylinder function W.

**scipy.special.pbdv**

`scipy.special.pbdv(v, x) = <ufunc 'pbdv'>`

Parabolic cylinder function D

Returns (d, dp) the parabolic cylinder function  $Dv(x)$  in d and the derivative,  $Dv'(x)$  in dp.

**Returns**

**d** Value of the function  
**dp** Value of the derivative vs x

**scipy.special.pbvv**

`scipy.special.pbvv(v, x) = <ufunc 'pbvv'>`

Parabolic cylinder function V

Returns the parabolic cylinder function  $Vv(x)$  in v and the derivative,  $Vv'(x)$  in vp.

**Returns**

**v** Value of the function  
**vp** Value of the derivative vs x

**scipy.special.pbwa**

`scipy.special.pbwa(a, x) = <ufunc 'pbwa'>`

Parabolic cylinder function W.

The function is a particular solution to the differential equation

$$y'' + \left(\frac{1}{4}x^2 - a\right)y = 0,$$

for a full definition see section 12.14 in [1].

**Parameters**

**a** [array\_like] Real parameter  
**x** [array\_like] Real argument

**Returns**

**w** [scalar or ndarray] Value of the function

**wp** [scalar or ndarray] Value of the derivative in x

### Notes

The function is a wrapper for a Fortran routine by Zhang and Jin [2]. The implementation is accurate only for  $|a|, |x| < 5$  and returns NaN outside that range.

**Mathieu and Related Functions**

<code>mathieu_a(m, q)</code>	Characteristic value of even Mathieu functions
<code>mathieu_b(m, q)</code>	Characteristic value of odd Mathieu functions

**scipy.special.mathieu\_a**`scipy.special.mathieu_a(m, q) = <ufunc 'mathieu_a'>`

Characteristic value of even Mathieu functions

Returns the characteristic value for the even solution,  $ce_m(z, q)$ , of Mathieu's equation.**scipy.special.mathieu\_b**`scipy.special.mathieu_b(m, q) = <ufunc 'mathieu_b'>`

Characteristic value of odd Mathieu functions

Returns the characteristic value for the odd solution,  $se_m(z, q)$ , of Mathieu's equation.

These are not universal functions:

<code>mathieu_even_coef(m, q)</code>	Fourier coefficients for even Mathieu and modified Mathieu functions.
<code>mathieu_odd_coef(m, q)</code>	Fourier coefficients for even Mathieu and modified Mathieu functions.

**scipy.special.mathieu\_even\_coef**`scipy.special.mathieu_even_coef(m, q)`

Fourier coefficients for even Mathieu and modified Mathieu functions.

The Fourier series of the even solutions of the Mathieu differential equation are of the form

$$ce_{2n}(z, q) = \sum_{k=0}^{\infty} A_{(2n)}^{(2k)} \cos 2kz$$

$$ce_{2n+1}(z, q) = \sum_{k=0}^{\infty} A_{(2n+1)}^{(2k+1)} \cos(2k+1)z$$

This function returns the coefficients  $A_{(2n)}^{(2k)}$  for even input  $m=2n$ , and the coefficients  $A_{(2n+1)}^{(2k+1)}$  for odd input  $m=2n+1$ .

**Parameters**

- m** [int] Order of Mathieu functions. Must be non-negative.
- q** [float (>=0)] Parameter of Mathieu functions. Must be non-negative.

**Returns**

- Ak** [ndarray] Even or odd Fourier coefficients, corresponding to even or odd m.

**References**

[1], [2]

**scipy.special.mathieu\_odd\_coef**

`scipy.special.mathieu_odd_coef(m, q)`

Fourier coefficients for even Mathieu and modified Mathieu functions.

The Fourier series of the odd solutions of the Mathieu differential equation are of the form

$$se_{2n+1}(z, q) = \sum_{k=0}^{\infty} B_{(2n+1)}^{(2k+1)} \sin(2k + 1)z$$

$$se_{2n+2}(z, q) = \sum_{k=0}^{\infty} B_{(2n+2)}^{(2k+2)} \sin(2k + 2)z$$

This function returns the coefficients  $B_{(2n+2)}^{(2k+2)}$  for even input  $m=2n+2$ , and the coefficients  $B_{(2n+1)}^{(2k+1)}$  for odd input  $m=2n+1$ .

**Parameters**

- m** [int] Order of Mathieu functions. Must be non-negative.
- q** [float (>=0)] Parameter of Mathieu functions. Must be non-negative.

**Returns**

- Bk** [ndarray] Even or odd Fourier coefficients, corresponding to even or odd m.

**References**

[1]

The following return both function and first derivative:

<code>mathieu_cem(m, q, x)</code>	Even Mathieu function and its derivative
<code>mathieu_sem(m, q, x)</code>	Odd Mathieu function and its derivative
<code>mathieu_modcem1(m, q, x)</code>	Even modified Mathieu function of the first kind and its derivative
<code>mathieu_modcem2(m, q, x)</code>	Even modified Mathieu function of the second kind and its derivative
<code>mathieu_modsem1(m, q, x)</code>	Odd modified Mathieu function of the first kind and its derivative
<code>mathieu_modsem2(m, q, x)</code>	Odd modified Mathieu function of the second kind and its derivative

**scipy.special.mathieu\_cem**

`scipy.special.mathieu_cem(m, q, x) = <ufunc 'mathieu_cem'>`

Even Mathieu function and its derivative

Returns the even Mathieu function,  $ce_m(x, q)$ , of order  $m$  and parameter  $q$  evaluated at  $x$  (given in degrees). Also returns the derivative with respect to  $x$  of  $ce_m(x, q)$

**Parameters**

<b>m</b>	Order of the function
<b>q</b>	Parameter of the function
<b>x</b>	Argument of the function, <i>given in degrees, not radians</i>

**Returns**

<b>y</b>	Value of the function
<b>yp</b>	Value of the derivative vs $x$

**scipy.special.mathieu\_sem**

`scipy.special.mathieu_sem(m, q, x) = <ufunc 'mathieu_sem'>`

Odd Mathieu function and its derivative

Returns the odd Mathieu function,  $se_m(x, q)$ , of order  $m$  and parameter  $q$  evaluated at  $x$  (given in degrees). Also returns the derivative with respect to  $x$  of  $se_m(x, q)$ .

**Parameters**

<b>m</b>	Order of the function
<b>q</b>	Parameter of the function
<b>x</b>	Argument of the function, <i>given in degrees, not radians</i> .

**Returns**

<b>y</b>	Value of the function
<b>yp</b>	Value of the derivative vs $x$

**scipy.special.mathieu\_modcem1**

`scipy.special.mathieu_modcem1(m, q, x) = <ufunc 'mathieu_modcem1'>`

Even modified Mathieu function of the first kind and its derivative

Evaluates the even modified Mathieu function of the first kind,  $Mc1m(x, q)$ , and its derivative at  $x$  for order  $m$  and parameter  $q$ .

**Returns**

<b>y</b>	Value of the function
<b>yp</b>	Value of the derivative vs $x$

**scipy.special.mathieu\_modcem2**

`scipy.special.mathieu_modcem2(m, q, x) = <ufunc 'mathieu_modcem2'>`

Even modified Mathieu function of the second kind and its derivative

Evaluates the even modified Mathieu function of the second kind,  $Mc2m(x, q)$ , and its derivative at  $x$  (given in degrees) for order  $m$  and parameter  $q$ .

**Returns**

<b>y</b>	Value of the function
<b>yp</b>	Value of the derivative vs $x$

### scipy.special.mathieu\_modsem1

`scipy.special.mathieu_modsem1(m, q, x) = <ufunc 'mathieu_modsem1'>`

Odd modified Mathieu function of the first kind and its derivative

Evaluates the odd modified Mathieu function of the first kind,  $Ms1m(x, q)$ , and its derivative at  $x$  (given in degrees) for order  $m$  and parameter  $q$ .

**Returns**

**y**            Value of the function  
**yp**           Value of the derivative vs x

### scipy.special.mathieu\_modsem2

`scipy.special.mathieu_modsem2(m, q, x) = <ufunc 'mathieu_modsem2'>`

Odd modified Mathieu function of the second kind and its derivative

Evaluates the odd modified Mathieu function of the second kind,  $Ms2m(x, q)$ , and its derivative at  $x$  (given in degrees) for order  $m$  and parameter  $q$ .

**Returns**

**y**            Value of the function  
**yp**           Value of the derivative vs x

## Spheroidal Wave Functions

<code>pro_ang1(m, n, c, x)</code>	Prolate spheroidal angular function of the first kind and its derivative
<code>pro_rad1(m, n, c, x)</code>	Prolate spheroidal radial function of the first kind and its derivative
<code>pro_rad2(m, n, c, x)</code>	Prolate spheroidal radial function of the second kind and its derivative
<code>obl_ang1(m, n, c, x)</code>	Oblate spheroidal angular function of the first kind and its derivative
<code>obl_rad1(m, n, c, x)</code>	Oblate spheroidal radial function of the first kind and its derivative
<code>obl_rad2(m, n, c, x)</code>	Oblate spheroidal radial function of the second kind and its derivative.
<code>pro_cv(m, n, c)</code>	Characteristic value of prolate spheroidal function
<code>obl_cv(m, n, c)</code>	Characteristic value of oblate spheroidal function
<code>pro_cv_seq(m, n, c)</code>	Characteristic values for prolate spheroidal wave functions.
<code>obl_cv_seq(m, n, c)</code>	Characteristic values for oblate spheroidal wave functions.

### scipy.special.pro\_ang1

`scipy.special.pro_ang1(m, n, c, x) = <ufunc 'pro_ang1'>`

Prolate spheroidal angular function of the first kind and its derivative

Computes the prolate spheroidal angular function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

**s**            Value of the function  
**sp**          Value of the derivative vs x

**scipy.special.pro\_rad1**

`scipy.special.pro_rad1(m, n, c, x) = <ufunc 'pro_rad1'>`  
 Prolate spheroidal radial function of the first kind and its derivative

Computes the prolate spheroidal radial function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

**s** Value of the function  
**sp** Value of the derivative vs  $x$

**scipy.special.pro\_rad2**

`scipy.special.pro_rad2(m, n, c, x) = <ufunc 'pro_rad2'>`  
 Prolate spheroidal radial function of the second kind and its derivative

Computes the prolate spheroidal radial function of the second kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

**s** Value of the function  
**sp** Value of the derivative vs  $x$

**scipy.special.obl\_ang1**

`scipy.special.obl_ang1(m, n, c, x) = <ufunc 'obl_ang1'>`  
 Oblate spheroidal angular function of the first kind and its derivative

Computes the oblate spheroidal angular function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

**s** Value of the function  
**sp** Value of the derivative vs  $x$

**scipy.special.obl\_rad1**

`scipy.special.obl_rad1(m, n, c, x) = <ufunc 'obl_rad1'>`  
 Oblate spheroidal radial function of the first kind and its derivative

Computes the oblate spheroidal radial function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

**s** Value of the function  
**sp** Value of the derivative vs  $x$

**scipy.special.obl\_rad2**

`scipy.special.obl_rad2(m, n, c, x) = <ufunc 'obl_rad2'>`  
 Oblate spheroidal radial function of the second kind and its derivative.

Computes the oblate spheroidal radial function of the second kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ .

**Returns**

**s** Value of the function  
**sp** Value of the derivative vs  $x$

### scipy.special.pro\_cv

`scipy.special.pro_cv(m, n, c) = <ufunc 'pro_cv'>`

Characteristic value of prolate spheroidal function

Computes the characteristic value of prolate spheroidal wave functions of order  $m, n$  ( $n \geq m$ ) and spheroidal parameter  $c$ .

### scipy.special.obl\_cv

`scipy.special.obl_cv(m, n, c) = <ufunc 'obl_cv'>`

Characteristic value of oblate spheroidal function

Computes the characteristic value of oblate spheroidal wave functions of order  $m, n$  ( $n \geq m$ ) and spheroidal parameter  $c$ .

### scipy.special.pro\_cv\_seq

`scipy.special.pro_cv_seq(m, n, c)`

Characteristic values for prolate spheroidal wave functions.

Compute a sequence of characteristic values for the prolate spheroidal wave functions for mode  $m$  and  $n'=m..n$  and spheroidal parameter  $c$ .

#### References

[1]

### scipy.special.obl\_cv\_seq

`scipy.special.obl_cv_seq(m, n, c)`

Characteristic values for oblate spheroidal wave functions.

Compute a sequence of characteristic values for the oblate spheroidal wave functions for mode  $m$  and  $n'=m..n$  and spheroidal parameter  $c$ .

#### References

[1]

<code>obl_rad1_cv(m, n, c, cv, x)</code>	Oblate spheroidal radial function <code>obl_rad1</code> for pre-computed characteristic value
<code>obl_rad2_cv(m, n, c, cv, x)</code>	Oblate spheroidal radial function <code>obl_rad2</code> for pre-computed characteristic value

**scipy.special.pro\_ang1\_cv**

`scipy.special.pro_ang1_cv(m, n, c, cv, x) = <ufunc 'pro_ang1_cv'>`

Prolate spheroidal angular function `pro_ang1` for precomputed characteristic value

Computes the prolate spheroidal angular function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ . Requires pre-computed characteristic value.

**Returns**

<b>s</b>	Value of the function
<b>sp</b>	Value of the derivative vs $x$

**scipy.special.pro\_rad1\_cv**

`scipy.special.pro_rad1_cv(m, n, c, cv, x) = <ufunc 'pro_rad1_cv'>`

Prolate spheroidal radial function `pro_rad1` for precomputed characteristic value

Computes the prolate spheroidal radial function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ . Requires pre-computed characteristic value.

**Returns**

<b>s</b>	Value of the function
<b>sp</b>	Value of the derivative vs $x$

**scipy.special.pro\_rad2\_cv**

`scipy.special.pro_rad2_cv(m, n, c, cv, x) = <ufunc 'pro_rad2_cv'>`

Prolate spheroidal radial function `pro_rad2` for precomputed characteristic value

Computes the prolate spheroidal radial function of the second kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ . Requires pre-computed characteristic value.

**Returns**

<b>s</b>	Value of the function
<b>sp</b>	Value of the derivative vs $x$

**scipy.special.obl\_ang1\_cv**

`scipy.special.obl_ang1_cv(m, n, c, cv, x) = <ufunc 'obl_ang1_cv'>`

Oblate spheroidal angular function `obl_ang1` for precomputed characteristic value

Computes the oblate spheroidal angular function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ . Requires pre-computed characteristic value.

**Returns**

<b>s</b>	Value of the function
<b>sp</b>	Value of the derivative vs $x$

**scipy.special.obl\_rad1\_cv**

`scipy.special.obl_rad1_cv(m, n, c, cv, x) = <ufunc 'obl_rad1_cv'>`

Oblate spheroidal radial function `obl_rad1` for precomputed characteristic value

Computes the oblate spheroidal radial function of the first kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ . Requires pre-computed characteristic value.

**Returns**

**s** Value of the function  
**sp** Value of the derivative vs  $x$

**scipy.special.obl\_rad2\_cv**

`scipy.special.obl_rad2_cv(m, n, c, cv, x) = <ufunc 'obl_rad2_cv'>`

Oblate spheroidal radial function `obl_rad2` for precomputed characteristic value

Computes the oblate spheroidal radial function of the second kind and its derivative (with respect to  $x$ ) for mode parameters  $m \geq 0$  and  $n \geq m$ , spheroidal parameter  $c$  and  $|x| < 1.0$ . Requires pre-computed characteristic value.

**Returns**

**s** Value of the function  
**sp** Value of the derivative vs  $x$

**Kelvin Functions**

<code>kelvin(x)</code>	Kelvin functions as complex numbers
<code>kelvin_zeros(nt)</code>	Compute $nt$ zeros of all Kelvin functions.
<code>ber(x)</code>	Kelvin function <code>ber</code> .
<code>bei(x)</code>	Kelvin function <code>bei</code>
<code>berp(x)</code>	Derivative of the Kelvin function <code>ber</code>
<code>beip(x)</code>	Derivative of the Kelvin function <code>bei</code>
<code>ker(x)</code>	Kelvin function <code>ker</code>
<code>kei(x)</code>	Kelvin function <code>ker</code>
<code>kerp(x)</code>	Derivative of the Kelvin function <code>ker</code>
<code>keip(x)</code>	Derivative of the Kelvin function <code>kei</code>

**scipy.special.kelvin**

`scipy.special.kelvin(x) = <ufunc 'kelvin'>`

Kelvin functions as complex numbers

**Returns**

**Be, Ke, Bep, Kep**

The tuple (Be, Ke, Bep, Kep) contains complex numbers representing the real and imaginary Kelvin functions and their derivatives evaluated at  $x$ . For example, `kelvin(x)[0].real = ber x` and `kelvin(x)[0].imag = bei x` with similar relationships for `ker` and `kei`.

**scipy.special.kelvin\_zeros**

`scipy.special.kelvin_zeros(nt)`

Compute  $nt$  zeros of all Kelvin functions.

Returned in a length-8 tuple of arrays of length  $nt$ . The tuple contains the arrays of zeros of (ber, bei, ker, kei, ber', bei', ker', kei').

## Combinatorics

<code>comb(N, k[, exact, repetition])</code>	The number of combinations of <i>N</i> things taken <i>k</i> at a time.
<code>perm(N, k[, exact])</code>	Permutations of <i>N</i> things taken <i>k</i> at a time, i.e., <i>k</i> -permutations of <i>N</i> .

## scipy.special.comb

`scipy.special.comb` (*N, k, exact=False, repetition=False*)

The number of combinations of *N* things taken *k* at a time.

This is often expressed as “*N* choose *k*”.

### Parameters

<b>N</b>	[int, ndarray] Number of things.
<b>k</b>	[int, ndarray] Number of elements taken.
<b>exact</b>	[bool, optional] If <i>exact</i> is False, then floating point precision is used, otherwise exact long integer is computed.
<b>repetition</b>	[bool, optional] If <i>repetition</i> is True, then the number of combinations with repetition is computed.

### Returns

<b>val</b>	[int, float, ndarray] The total number of combinations.
------------	---------------------------------------------------------

See also:

### `binom`

Binomial coefficient ufunc

### Notes

- Array arguments accepted only for *exact=False* case.
- If  $k > N$ ,  $N < 0$ , or  $k < 0$ , then a 0 is returned.

### Examples

```
>>> from scipy.special import comb
>>> k = np.array([3, 4])
>>> n = np.array([10, 10])
>>> comb(n, k, exact=False)
array([120., 210.]
```

(continues on next page)

(continued from previous page)

```
>>> comb(10, 3, exact=True)
120L
>>> comb(10, 3, exact=True, repetition=True)
220L
```

**scipy.special.perm**`scipy.special.perm(N, k, exact=False)`

Permutations of N things taken k at a time, i.e., k-permutations of N.

It's also known as "partial permutations".

**Parameters**

**N** [int, ndarray] Number of things.  
**k** [int, ndarray] Number of elements taken.  
**exact** [bool, optional] If *exact* is False, then floating point precision is used, otherwise exact long integer is computed.

**Returns****val** [int, ndarray] The number of k-permutations of N.**Notes**

- Array arguments accepted only for `exact=False` case.
- If  $k > N$ ,  $N < 0$ , or  $k < 0$ , then a 0 is returned.

**Examples**

```
>>> from scipy.special import perm
>>> k = np.array([3, 4])
>>> n = np.array([10, 10])
>>> perm(n, k)
array([720., 5040.])
>>> perm(10, 3, exact=True)
720
```

**Lambert W and Related Functions**

---

<code>lambertw(z[, k, tol])</code>	Lambert W function.
<code>wrightomega(z[, out])</code>	Wright Omega function.

---

**scipy.special.lambertw**`scipy.special.lambertw(z, k=0, tol=1e-8)`

Lambert W function.

The Lambert W function  $W(z)$  is defined as the inverse function of  $w * \exp(w)$ . In other words, the value of  $W(z)$  is such that  $z = W(z) * \exp(W(z))$  for any complex number  $z$ .

The Lambert W function is a multivalued function with infinitely many branches. Each branch gives a separate

solution of the equation  $z = w \exp(w)$ . Here, the branches are indexed by the integer  $k$ .

#### Parameters

<b>z</b>	[array_like] Input argument.
<b>k</b>	[int, optional] Branch index.
<b>tol</b>	[float, optional] Evaluation tolerance.

#### Returns

<b>w</b>	[array] $w$ will have the same shape as $z$ .
----------	-----------------------------------------------

See also:

#### `wrightomega`

the Wright Omega function

#### Notes

All branches are supported by `lambertw`:

- `lambertw(z)` gives the principal solution (branch 0)
- `lambertw(z, k)` gives the solution on branch  $k$

The Lambert W function has two partially real branches: the principal branch ( $k = 0$ ) is real for real  $z > -1/e$ , and the  $k = -1$  branch is real for  $-1/e < z < 0$ . All branches except  $k = 0$  have a logarithmic singularity at  $z = 0$ .

#### Possible issues

The evaluation can become inaccurate very close to the branch point at  $-1/e$ . In some corner cases, `lambertw` might currently fail to converge, or can end up on the wrong branch.

#### Algorithm

Halley's iteration is used to invert  $w * \exp(w)$ , using a first-order asymptotic approximation ( $O(\log(w))$  or  $O(w)$ ) as the initial estimate.

The definition, implementation and choice of branches is based on [2].

#### References

[1], [2]

#### Examples

The Lambert W function is the inverse of  $w \exp(w)$ :

```
>>> from scipy.special import lambertw
>>> w = lambertw(1)
>>> w
(0.56714329040978384+0j)
>>> w * np.exp(w)
(1.0+0j)
```

Any branch gives a valid inverse:

```
>>> w = lambertw(1, k=3)
>>> w
(-2.8535817554090377+17.113535539412148j)
>>> w*np.exp(w)
(1.0000000000000002+1.609823385706477e-15j)
```

### Applications to equation-solving

The Lambert W function may be used to solve various kinds of equations, such as finding the value of the infinite power tower  $z^{z^{z^{\dots}}}$ :

```
>>> def tower(z, n):
... if n == 0:
... return z
... return z ** tower(z, n-1)
...
>>> tower(0.5, 100)
0.641185744504986
>>> -lambertw(-np.log(0.5)) / np.log(0.5)
(0.64118574450498589+0j)
```

### scipy.special.wrightomega

`scipy.special.wrightomega(z, out=None) = <ufunc 'wrightomega'>`  
 Wright Omega function.

Defined as the solution to

$$\omega + \log(\omega) = z$$

where  $\log$  is the principal branch of the complex logarithm.

#### Parameters

**z** [array\_like] Points at which to evaluate the Wright Omega function

#### Returns

**omega** [ndarray] Values of the Wright Omega function

See also:

#### [lambertw](#)

The Lambert W function

### Notes

New in version 0.19.0.

The function can also be defined as

$$\omega(z) = W_{K(z)}(e^z)$$

where  $K(z) = \lceil (\Im(z) - \pi)/(2\pi) \rceil$  is the unwinding number and  $W$  is the Lambert W function.

The implementation here is taken from [1].

<code>binom(n, k)</code>	Binomial coefficient
<code>diric(x, n)</code>	Periodic sinc function, also called the Dirichlet function.
<code>euler(n)</code>	Euler numbers $E(0), E(1), \dots, E(n)$ .
<code>expn(n, x)</code>	Exponential integral $E_n$
<code>exp1(z)</code>	Exponential integral $E_1$ of complex argument $z$
<code>expi(x)</code>	Exponential integral $Ei$
<code>factorial(n[, exact])</code>	The factorial of a number or array of numbers.
<code>factorial2(n[, exact])</code>	Double factorial.
<code>factorialk(n, k[, exact])</code>	Multifactorial of $n$ of order $k, n(!\dots!)$ .
<code>shichi(x[, out])</code>	Hyperbolic sine and cosine integrals.
<code>sici(x[, out])</code>	Sine and cosine integrals.
<code>softmax(x[, axis])</code>	Softmax function
<code>spence(z[, out])</code>	Spence's function, also known as the dilogarithm.
<code>zeta(x[, q, out])</code>	Riemann or Hurwitz zeta function.
<code>zetac(x)</code>	Riemann zeta function minus 1.

## scipy.special.agm

`scipy.special.agm(a, b) = <ufunc 'agm'>`

Compute the arithmetic-geometric mean of  $a$  and  $b$ .

Start with  $a_0 = a$  and  $b_0 = b$  and iteratively compute:

$$\begin{aligned} a_{n+1} &= (a_n + b_n) / 2 \\ b_{n+1} &= \sqrt{a_n * b_n} \end{aligned}$$

$a_n$  and  $b_n$  converge to the same limit as  $n$  increases; their common limit is  $\text{agm}(a, b)$ .

### Parameters

**a, b** [array\_like] Real values only. If the values are both negative, the result is negative. If one value is negative and the other is positive, *nan* is returned.

### Returns

**float** The arithmetic-geometric mean of  $a$  and  $b$ .

## Examples

```
>>> from scipy.special import agm
>>> a, b = 24.0, 6.0
>>> agm(a, b)
13.458171481725614
```

Compare that result to the iteration:

```
>>> while a != b:
... a, b = (a + b)/2, np.sqrt(a*b)
... print("a = %19.16f b=%19.16f" % (a, b))
...
a = 15.000000000000000000 b=12.000000000000000000
a = 13.500000000000000000 b=13.4164078649987388
a = 13.4582039324993694 b=13.4581390309909850
a = 13.4581714817451772 b=13.4581714817060547
a = 13.4581714817256159 b=13.4581714817256159
```

When array-like arguments are given, broadcasting applies:

```
>>> a = np.array([[1.5], [3], [6]]) # a has shape (3, 1).
>>> b = np.array([6, 12, 24, 48]) # b has shape (4,).
>>> agm(a, b)
array([[3.36454287, 5.42363427, 9.05798751, 15.53650756],
 [4.37037309, 6.72908574, 10.84726853, 18.11597502],
 [6. , 8.74074619, 13.45817148, 21.69453707]])
```

### scipy.special.bernoulli

`scipy.special.bernoulli`(*n*)  
Bernoulli numbers B<sub>0</sub>..B<sub>n</sub> (inclusive).

#### References

[1]

### scipy.special.binom

`scipy.special.binom`(*n*, *k*) = <ufunc 'binom'>  
Binomial coefficient

**See also:**

[comb](#)

The number of combinations of N things taken k at a time.

### scipy.special.diric

`scipy.special.diric`(*x*, *n*)  
Periodic sinc function, also called the Dirichlet function.

The Dirichlet function is defined as:

$$\text{diric}(x, n) = \sin(x * n/2) / (n * \sin(x / 2)),$$

where *n* is a positive integer.

#### Parameters

**x** [array\_like] Input data  
**n** [int] Integer defining the periodicity.

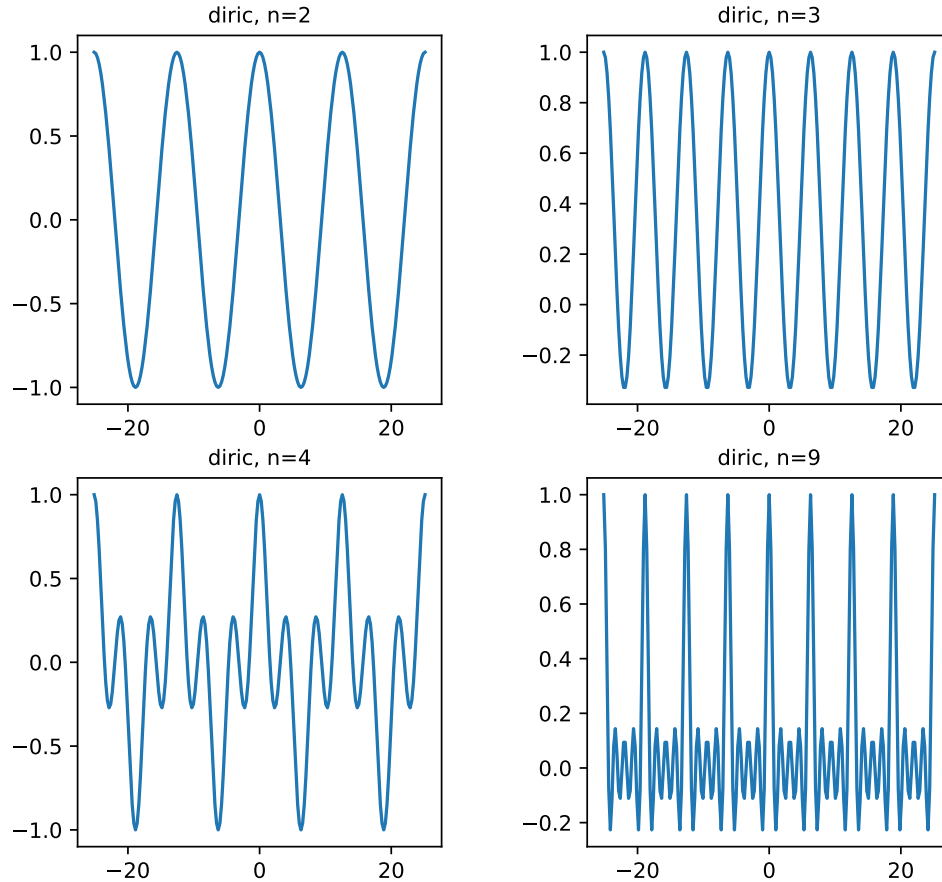

#### Returns

**diric** [ndarray]

## Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
```

```
>>> x = np.linspace(-8*np.pi, 8*np.pi, num=201)
>>> plt.figure(figsize=(8, 8));
>>> for idx, n in enumerate([2, 3, 4, 9]):
... plt.subplot(2, 2, idx+1)
... plt.plot(x, special.diric(x, n))
... plt.title('diric, n={}'.format(n))
>>> plt.show()
```

The following example demonstrates that `diric` gives the magnitudes (modulo the sign and scaling) of the Fourier coefficients of a rectangular pulse.

Suppress output of values that are effectively 0:

```
>>> np.set_printoptions(suppress=True)
```

Create a signal  $x$  of length  $m$  with  $k$  ones:

```
>>> m = 8
>>> k = 3
>>> x = np.zeros(m)
>>> x[:k] = 1
```

Use the FFT to compute the Fourier transform of  $x$ , and inspect the magnitudes of the coefficients:

```
>>> np.abs(np.fft.fft(x))
array([3. , 2.41421356, 1. , 0.41421356, 1. ,
 0.41421356, 1. , 2.41421356])
```

Now find the same values (up to sign) using `diric`. We multiply by  $k$  to account for the different scaling conventions of `numpy.fft.fft` and `diric`:

```
>>> theta = np.linspace(0, 2*np.pi, m, endpoint=False)
>>> k * special.diric(theta, k)
array([3. , 2.41421356, 1. , -0.41421356, -1. ,
 -0.41421356, 1. , 2.41421356])
```

## scipy.special.euler

`scipy.special.euler(n)`

Euler numbers  $E(0)$ ,  $E(1)$ , ...,  $E(n)$ .

The Euler numbers [1] are also known as the secant numbers.

Because `euler(n)` returns floating point values, it does not give exact values for large  $n$ . The first inexact value is  $E(22)$ .

### Parameters

**n** [int] The highest index of the Euler number to be returned.

### Returns

**ndarray** The Euler numbers  $[E(0), E(1), \dots, E(n)]$ . The odd Euler numbers, which are all zero, are included.

## References

[1], [2]

## Examples

```
>>> from scipy.special import euler
>>> euler(6)
array([1., 0., -1., 0., 5., 0., -61.])
```

```
>>> euler(13).astype(np.int64)
array([[1, 0, -1, 0, 5, 0, -61,
 0, 1385, 0, -50521, 0, 2702765, 0]])
```

```
>>> euler(22)[-1] # Exact value of E(22) is -69348874393137901.
-69348874393137976.0
```

### scipy.special.expn

`scipy.special.expn(n, x) = <ufunc 'expn'>`  
Exponential integral  $E_n$

Returns the exponential integral for integer  $n$  and non-negative  $x$  and  $n$ :

```
integral(exp(-x*t) / t**n, t=1..inf).
```

### scipy.special.exp1

`scipy.special.exp1(z) = <ufunc 'exp1'>`  
Exponential integral  $E_1$  of complex argument  $z$

```
integral(exp(-z*t)/t, t=1..inf).
```

### scipy.special.expi

`scipy.special.expi(x) = <ufunc 'expi'>`  
Exponential integral  $E_i$

Defined as:

```
integral(exp(t)/t, t=-inf..x)
```

See [expn](#) for a different exponential integral.

### scipy.special.factorial

`scipy.special.factorial(n, exact=False)`  
The factorial of a number or array of numbers.

The factorial of non-negative integer  $n$  is the product of all positive integers less than or equal to  $n$ :

```
n! = n * (n - 1) * (n - 2) * ... * 1
```

#### Parameters

- n** [int or array\_like of ints] Input values. If  $n < 0$ , the return value is 0.
- exact** [bool, optional] If True, calculate the answer exactly using long integer arithmetic. If False, result is approximated in floating point rapidly using the [gamma](#) function. Default is False.

#### Returns

- nf** [float or int or ndarray] Factorial of  $n$ , as integer or float depending on *exact*.

#### Notes

For arrays with `exact=True`, the factorial is computed only once, for the largest input, with each other result computed in the process. The output dtype is increased to `int64` or `object` if necessary.

With `exact=False` the factorial is approximated using the gamma function:

$$n! = \Gamma(n + 1)$$

## Examples

```
>>> from scipy.special import factorial
>>> arr = np.array([3, 4, 5])
>>> factorial(arr, exact=False)
array([6., 24., 120.])
>>> factorial(arr, exact=True)
array([6, 24, 120])
>>> factorial(5, exact=True)
120L
```

## scipy.special.factorial2

`scipy.special.factorial2` (*n*, *exact=False*)

Double factorial.

This is the factorial with every second value skipped. E.g.,  $7!! = 7 * 5 * 3 * 1$ . It can be approximated numerically as:

$$\begin{aligned} n!! &= \text{special.gamma}(n/2+1) * 2^{(m+1)/2} / \text{sqrt}(\text{pi}) & n \text{ odd} \\ &= 2^{(n/2)} * (n/2)! & n \text{ even} \end{aligned}$$

### Parameters

- n** [int or array\_like] Calculate  $n!!$ . Arrays are only supported with *exact* set to `False`. If  $n < 0$ , the return value is 0.
- exact** [bool, optional] The result can be approximated rapidly using the gamma-formula above (default). If *exact* is set to `True`, calculate the answer exactly using integer arithmetic.

### Returns

- nff** [float or int] Double factorial of *n*, as an int or a float depending on *exact*.

## Examples

```
>>> from scipy.special import factorial2
>>> factorial2(7, exact=False)
array(105.00000000000001)
>>> factorial2(7, exact=True)
105L
```

## scipy.special.factorialk

`scipy.special.factorialk` (*n*, *k*, *exact=True*)

Multifactorial of *n* of order *k*,  $n(!!\dots!)$ .

This is the multifactorial of *n* skipping *k* values. For example,

$$\text{factorialk}(17, 4) = 17!!!! = 17 * 13 * 9 * 5 * 1$$

In particular, for any integer *n*, we have

factorialk(n, 1) = factorial(n)  
 factorialk(n, 2) = factorial2(n)

**Parameters**

**n** [int] Calculate multifactorial. If  $n < 0$ , the return value is 0.  
**k** [int] Order of multifactorial.  
**exact** [bool, optional] If exact is set to True, calculate the answer exactly using integer arithmetic.

**Returns**

**val** [int] Multifactorial of  $n$ .

**Raises**

**NotImplementedError**  
 Raises when exact is False

**Examples**

```
>>> from scipy.special import factorialk
>>> factorialk(5, 1, exact=True)
120L
>>> factorialk(5, 3, exact=True)
10L
```

**scipy.special.shichi**

scipy.special.**shichi**(x, out=None) = <ufunc 'shichi'>  
 Hyperbolic sine and cosine integrals.

The hyperbolic sine integral is

$$\int_0^x \frac{\sinh t}{t} dt$$

and the hyperbolic cosine integral is

$$\gamma + \log(x) + \int_0^x \frac{\cosh t - 1}{t} dt$$

where  $\gamma$  is Euler's constant and log is the principle branch of the logarithm.

**Parameters**

**x** [array\_like] Real or complex points at which to compute the hyperbolic sine and cosine integrals.

**Returns**

**si** [ndarray] Hyperbolic sine integral at x  
**ci** [ndarray] Hyperbolic cosine integral at x

**Notes**

For real arguments with  $x < 0$ , chi is the real part of the hyperbolic cosine integral. For such points  $\text{chi}(x)$  and  $\text{chi}(x + 0j)$  differ by a factor of  $1j \cdot \pi$ .

For real arguments the function is computed by calling Cephes' [1] *shichi* routine. For complex arguments the algorithm is based on Mpmath's [2] *shi* and *chi* routines.

## References

[1], [2]

### scipy.special.sici

`scipy.special.sici(x, out=None) = <ufunc 'sici'>`

Sine and cosine integrals.

The sine integral is

$$\int_0^x \frac{\sin t}{t} dt$$

and the cosine integral is

$$\gamma + \log(x) + \int_0^x \frac{\cos t - 1}{t} dt$$

where  $\gamma$  is Euler's constant and  $\log$  is the principle branch of the logarithm.

#### Parameters

**x** [array\_like] Real or complex points at which to compute the sine and cosine integrals.

#### Returns

**si** [ndarray] Sine integral at  $x$   
**ci** [ndarray] Cosine integral at  $x$

## Notes

For real arguments with  $x < 0$ , `ci` is the real part of the cosine integral. For such points `ci(x)` and `ci(x + 0j)` differ by a factor of  $1j\pi$ .

For real arguments the function is computed by calling Cephes' [1] `sici` routine. For complex arguments the algorithm is based on Mpmath's [2] `si` and `ci` routines.

## References

[1], [2]

### scipy.special.softmax

`scipy.special.softmax(x, axis=None)`

Softmax function

The softmax function transforms each element of a collection by computing the exponential of each element divided by the sum of the exponentials of all the elements. That is, if  $x$  is a one-dimensional numpy array:

$$\text{softmax}(x) = \text{np.exp}(x) / \text{sum}(\text{np.exp}(x))$$

#### Parameters

**x** [array\_like] Input array.  
**axis** [int or tuple of ints, optional] Axis to compute values along. Default is None and softmax will be computed over the entire array  $x$ .

#### Returns

**s** [ndarray] An array the same shape as  $x$ . The result will sum to 1 along the specified axis.

## Notes

The formula for the softmax function  $\sigma(x)$  for a vector  $x = \{x_0, x_1, \dots, x_{n-1}\}$  is

$$\sigma(x)_j = \frac{e^{x_j}}{\sum_k e^{x_k}}$$

The `softmax` function is the gradient of `logsumexp`.

New in version 1.2.0.

## Examples

```
>>> from scipy.special import softmax
>>> np.set_printoptions(precision=5)
```

```
>>> x = np.array([[1, 0.5, 0.2, 3],
... [1, -1, 7, 3],
... [2, 12, 13, 3]])
...
```

Compute the softmax transformation over the entire array.

```
>>> m = softmax(x)
>>> m
array([[4.48309e-06, 2.71913e-06, 2.01438e-06, 3.31258e-05],
 [4.48309e-06, 6.06720e-07, 1.80861e-03, 3.31258e-05],
 [1.21863e-05, 2.68421e-01, 7.29644e-01, 3.31258e-05]])
```

```
>>> m.sum()
1.0000000000000002
```

Compute the softmax transformation along the first axis (i.e. the columns).

```
>>> m = softmax(x, axis=0)
```

```
>>> m
array([[2.11942e-01, 1.01300e-05, 2.75394e-06, 3.33333e-01],
 [2.11942e-01, 2.26030e-06, 2.47262e-03, 3.33333e-01],
 [5.76117e-01, 9.99988e-01, 9.97525e-01, 3.33333e-01]])
```

```
>>> m.sum(axis=0)
array([1., 1., 1., 1.])
```

Compute the softmax transformation along the second axis (i.e. the rows).

```
>>> m = softmax(x, axis=1)
>>> m
array([[1.05877e-01, 6.42177e-02, 4.75736e-02, 7.82332e-01],
 [2.42746e-03, 3.28521e-04, 9.79307e-01, 1.79366e-02],
 [1.22094e-05, 2.68929e-01, 7.31025e-01, 3.31885e-05]])
```

```
>>> m.sum(axis=1)
array([1., 1., 1.])
```

### scipy.special.spence

`scipy.special.spence` (*z*, *out=None*) = <ufunc 'spence'>

Spence's function, also known as the dilogarithm.

It is defined to be

$$\int_0^z \frac{\log(t)}{1-t} dt$$

for complex *z*, where the contour of integration is taken to avoid the branch cut of the logarithm. Spence's function is analytic everywhere except the negative real axis where it has a branch cut.

#### Parameters

**z** [array\_like] Points at which to evaluate Spence's function

#### Returns

**s** [ndarray] Computed values of Spence's function

### Notes

There is a different convention which defines Spence's function by the integral

$$-\int_0^z \frac{\log(1-t)}{t} dt;$$

this is our `spence(1 - z)`.

### scipy.special.zeta

`scipy.special.zeta` (*x*, *q=None*, *out=None*)

Riemann or Hurwitz zeta function.

#### Parameters

**x** [array\_like of float] Input data, must be real  
**q** [array\_like of float, optional] Input data, must be real. Defaults to Riemann zeta.  
**out** [ndarray, optional] Output array for the computed values.

#### Returns

**out** [array\_like] Values of zeta(x).

See also:

`zetac`

### Notes

The two-argument version is the Hurwitz zeta function:

$$\zeta(x, q) = \sum_{k=0}^{\infty} \frac{1}{(k+q)^x},$$

Riemann zeta function corresponds to  $q = 1$ .

## Examples

```
>>> from scipy.special import zeta, polygamma, factorial
```

Some specific values:

```
>>> zeta(2), np.pi**2/6
(1.6449340668482266, 1.6449340668482264)
```

```
>>> zeta(4), np.pi**4/90
(1.0823232337111381, 1.082323233711138)
```

Relation to the *polygamma* function:

```
>>> m = 3
>>> x = 1.25
>>> polygamma(m, x)
array(2.782144009188397)
>>> (-1)**(m+1) * factorial(m) * zeta(m+1, x)
2.7821440091883969
```

## scipy.special.zetac

`scipy.special.zetac(x) = <ufunc 'zetac'>`

Riemann zeta function minus 1.

This function is defined as

$$\zeta(x) = \sum_{k=2}^{\infty} 1/k^x,$$

where  $x > 1$ . For  $x < 1$ , the analytic continuation is computed.

Because of limitations of the numerical algorithm, `zetac(x)` returns *nan* for  $x$  less than -30.8148.

### Parameters

**x** [array\_like of float] Values at which to compute  $\zeta(x) - 1$  (must be real).

### Returns

**out** [array\_like] Values of  $\zeta(x) - 1$ .

See also:

[\*zeta\*](#)

## Examples

```
>>> from scipy.special import zetac, zeta
```

Some special values:

```
>>> zetac(2), np.pi**2/6 - 1
(0.64493406684822641, 0.6449340668482264)
```

```
>>> zetac(-1), -1.0/12 - 1
(-1.0833333333333333, -1.0833333333333333)
```

Compare `zetac(x)` to `zeta(x) - 1` for large  $x$ :

```
>>> zetac(60), zeta(60) - 1
(8.673617380119933e-19, 0.0)
```

## Convenience Functions

<code>cbrt(x)</code>	Element-wise cube root of $x$ .
<code>exp10(x)</code>	Compute $10^{**x}$ element-wise.
<code>exp2(x)</code>	Compute $2^{**x}$ element-wise.
<code>radian(d, m, s)</code>	Convert from degrees to radians
<code>cosdg(x)</code>	Cosine of the angle $x$ given in degrees.
<code>sindg(x)</code>	Sine of angle given in degrees
<code>tandg(x)</code>	Tangent of angle $x$ given in degrees.
<code>cotdg(x)</code>	Cotangent of the angle $x$ given in degrees.
<code>log1p(x)</code>	Calculates $\log(1+x)$ for use when $x$ is near zero
<code>expm1(x)</code>	Compute $\exp(x) - 1$ .
<code>cosm1(x)</code>	$\cos(x) - 1$ for use when $x$ is near zero.
<code>round(x)</code>	Round to nearest integer
<code>xlogy(x, y)</code>	Compute $x \cdot \log(y)$ so that the result is 0 if $x = 0$ .
<code>xlog1py(x, y)</code>	Compute $x \cdot \log_{1p}(y)$ so that the result is 0 if $x = 0$ .
<code>logsumexp(a[, axis, b, keepdims, return_sign])</code>	Compute the log of the sum of exponentials of input elements.
<code>exprel(x)</code>	Relative error exponential, $(\exp(x) - 1)/x$ .
<code>sinc(x)</code>	Return the sinc function.

## scipy.special.cbirt

`scipy.special.cbirt(x) = <ufunc 'cbirt'>`

Element-wise cube root of  $x$ .

### Parameters

**x** [array\_like]  $x$  must contain real numbers.

### Returns

**float** The cube root of each value in  $x$ .

## Examples

```
>>> from scipy.special import cbirt
```

```
>>> cbirt(8)
2.0
>>> cbirt([-8, -3, 0.125, 1.331])
array([-2. , -1.44224957, 0.5 , 1.1])
```

**scipy.special.exp10**

`scipy.special.exp10(x) = <ufunc 'exp10'>`  
 Compute  $10^{**x}$  element-wise.

**Parameters**

**x** [array\_like]  $x$  must contain real numbers.

**Returns**

**float**  $10^{**x}$ , computed element-wise.

**Examples**

```
>>> from scipy.special import exp10
```

```
>>> exp10(3)
1000.0
>>> x = np.array([[-1, -0.5, 0], [0.5, 1, 1.5]])
>>> exp10(x)
array([[0.1 , 0.31622777, 1.],
 [3.16227766, 10. , 31.6227766]])
```

**scipy.special.exp2**

`scipy.special.exp2(x) = <ufunc 'exp2'>`  
 Compute  $2^{**x}$  element-wise.

**Parameters**

**x** [array\_like]  $x$  must contain real numbers.

**Returns**

**float**  $2^{**x}$ , computed element-wise.

**Examples**

```
>>> from scipy.special import exp2
```

```
>>> exp2(3)
8.0
>>> x = np.array([[-1, -0.5, 0], [0.5, 1, 1.5]])
>>> exp2(x)
array([[0.5 , 0.70710678, 1.],
 [1.41421356, 2. , 2.82842712]])
```

**scipy.special.radians**

`scipy.special.radians(d, m, s) = <ufunc 'radians'>`  
 Convert from degrees to radians

Returns the angle given in (d)egrees, (m)inutes, and (s)econds in radians.

**scipy.special.cosdg**

`scipy.special.cosdg(x)` = <ufunc 'cosdg'>  
Cosine of the angle  $x$  given in degrees.

**scipy.special.sindg**

`scipy.special.sindg(x)` = <ufunc 'sindg'>  
Sine of angle given in degrees

**scipy.special.tandg**

`scipy.special.tandg(x)` = <ufunc 'tandg'>  
Tangent of angle  $x$  given in degrees.

**scipy.special.cotdg**

`scipy.special.cotdg(x)` = <ufunc 'cotdg'>  
Cotangent of the angle  $x$  given in degrees.

**scipy.special.log1p**

`scipy.special.log1p(x)` = <ufunc 'log1p'>  
Calculates  $\log(1+x)$  for use when  $x$  is near zero

**scipy.special.expm1**

`scipy.special.expm1(x)` = <ufunc 'expm1'>  
Compute  $\exp(x) - 1$ .

When  $x$  is near zero,  $\exp(x)$  is near 1, so the numerical calculation of  $\exp(x) - 1$  can suffer from catastrophic loss of precision. `expm1(x)` is implemented to avoid the loss of precision that occurs when  $x$  is near zero.

**Parameters**

**x** [array\_like]  $x$  must contain real numbers.

**Returns**

**float**  $\exp(x) - 1$  computed element-wise.

**Examples**

```
>>> from scipy.special import expm1
```

```
>>> expm1(1.0)
1.7182818284590451
>>> expm1([-0.2, -0.1, 0, 0.1, 0.2])
array([-0.18126925, -0.09516258, 0. , 0.10517092, 0.22140276])
```

The exact value of  $\exp(7.5e-13) - 1$  is:

```
7.5000000000028125000000007031250000001318...*10**-13.
```

Here is what `expm1(7.5e-13)` gives:

```
>>> expm1(7.5e-13)
7.5000000000028135e-13
```

Compare that to  $\exp(7.5e-13) - 1$ , where the subtraction results in a “catastrophic” loss of precision:

```
>>> np.exp(7.5e-13) - 1
7.5006667543675576e-13
```

### scipy.special.cosm1

`scipy.special.cosm1(x)` = <ufunc 'cosm1'>  
 $\cos(x) - 1$  for use when  $x$  is near zero.

### scipy.special.round

`scipy.special.round(x)` = <ufunc 'round'>  
 Round to nearest integer

Returns the nearest integer to  $x$  as a double precision floating point result. If  $x$  ends in 0.5 exactly, the nearest even integer is chosen.

### scipy.special.xlogy

`scipy.special.xlogy(x, y)` = <ufunc 'xlogy'>  
 Compute  $x \cdot \log(y)$  so that the result is 0 if  $x = 0$ .

#### Parameters

**x** [array\_like] Multiplier  
**y** [array\_like] Argument

#### Returns

**z** [array\_like] Computed  $x \cdot \log(y)$

#### Notes

New in version 0.13.0.

### scipy.special.xlog1py

`scipy.special.xlog1py(x, y)` = <ufunc 'xlog1py'>  
 Compute  $x \cdot \log_{1p}(y)$  so that the result is 0 if  $x = 0$ .

#### Parameters

**x** [array\_like] Multiplier  
**y** [array\_like] Argument

#### Returns

**z** [array\_like] Computed  $x \cdot \log_{1p}(y)$

#### Notes

New in version 0.13.0.

**scipy.special.logsumexp**

`scipy.special.logsumexp(a, axis=None, b=None, keepdims=False, return_sign=False)`

Compute the log of the sum of exponentials of input elements.

**Parameters**

- a** [array\_like] Input array.
- axis** [None or int or tuple of ints, optional] Axis or axes over which the sum is taken. By default *axis* is None, and all elements are summed.  
New in version 0.11.0.
- keepdims** [bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original array.  
New in version 0.15.0.
- b** [array-like, optional] Scaling factor for  $\exp(a)$  must be of the same shape as *a* or broadcastable to *a*. These values may be negative in order to implement subtraction.  
New in version 0.12.0.
- return\_sign** [bool, optional] If this is set to True, the result will be a pair containing sign information; if False, results that are negative will be returned as NaN. Default is False (no sign information).  
New in version 0.16.0.

**Returns**

- res** [ndarray] The result,  $\text{np.log}(\text{np.sum}(\text{np.exp}(a)))$  calculated in a numerically more stable way. If *b* is given then  $\text{np.log}(\text{np.sum}(b*\text{np.exp}(a)))$  is returned.
- sgn** [ndarray] If `return_sign` is True, this will be an array of floating-point numbers matching `res` and +1, 0, or -1 depending on the sign of the result. If False, only one result is returned.

**See also:**

`numpy.logaddexp`, `numpy.logaddexp2`

**Notes**

NumPy has a `logaddexp` function which is very similar to `logsumexp`, but only handles two arguments. `logaddexp.reduce` is similar to this function, but may be less stable.

**Examples**

```
>>> from scipy.special import logsumexp
>>> a = np.arange(10)
>>> np.log(np.sum(np.exp(a)))
9.4586297444267107
>>> logsumexp(a)
9.4586297444267107
```

With weights

```
>>> a = np.arange(10)
>>> b = np.arange(10, 0, -1)
>>> logsumexp(a, b=b)
9.9170178533034665
```

(continues on next page)

(continued from previous page)

```
>>> np.log(np.sum(b*np.exp(a)))
9.9170178533034647
```

Returning a sign flag

```
>>> logsumexp([1,2],b=[1,-1],return_sign=True)
(1.5413248546129181, -1.0)
```

Notice that `logsumexp` does not directly support masked arrays. To use it on a masked array, convert the mask into zero weights:

```
>>> a = np.ma.array([np.log(2), 2, np.log(3)],
... mask=[False, True, False])
>>> b = (~a.mask).astype(int)
>>> logsumexp(a.data, b=b), np.log(5)
1.6094379124341005, 1.6094379124341005
```

### scipy.special.exprel

`scipy.special.exprel(x) = <ufunc 'exprel'>`

Relative error exponential,  $(\exp(x) - 1)/x$ .

When  $x$  is near zero,  $\exp(x)$  is near 1, so the numerical calculation of  $\exp(x) - 1$  can suffer from catastrophic loss of precision. `exprel(x)` is implemented to avoid the loss of precision that occurs when  $x$  is near zero.

#### Parameters

**x** [ndarray] Input array.  $x$  must contain real numbers.

#### Returns

**float**  $(\exp(x) - 1)/x$ , computed element-wise.

**See also:**

`expm1`

#### Notes

New in version 0.17.0.

#### Examples

```
>>> from scipy.special import exprel
```

```
>>> exprel(0.01)
1.0050167084168056
>>> exprel([-0.25, -0.1, 0, 0.1, 0.25])
array([0.88479687, 0.95162582, 1. , 1.05170918, 1.13610167])
```

Compare `exprel(5e-9)` to the naive calculation. The exact value is `1.00000000250000000416...`

```
>>> exprel(5e-9)
1.0000000025
```

```
>>> (np.exp(5e-9) - 1)/5e-9
0.99999999392252903
```

### scipy.special.sinc

`scipy.special.sinc(x)`

Return the sinc function.

The sinc function is  $\sin(\pi x)/(\pi x)$ .

#### Parameters

**x** [ndarray] Array (possibly multi-dimensional) of values for which to calculate `sinc(x)`.

#### Returns

**out** [ndarray] `sinc(x)`, which has the same shape as the input.

### Notes

`sinc(0)` is the limit value 1.

The name `sinc` is short for “sine cardinal” or “sinus cardinalis”.

The sinc function is used in various signal processing applications, including in anti-aliasing, in the construction of a Lanczos resampling filter, and in interpolation.

For bandlimited interpolation of discrete-time signals, the ideal interpolation kernel is proportional to the sinc function.

### References

[1], [2]

### Examples

```
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-4, 4, 41)
>>> np.sinc(x)
array([-3.89804309e-17, -4.92362781e-02, -8.40918587e-02, # may vary
 -8.90384387e-02, -5.84680802e-02, 3.89804309e-17,

 8.50444803e-02, -3.89804309e-17, -1.03943254e-01,
 -1.89206682e-01, -2.16236208e-01, -1.55914881e-01,
 3.89804309e-17, 2.33872321e-01, 5.04551152e-01,
 7.56826729e-01, 9.35489284e-01, 1.00000000e+00,
 9.35489284e-01, 7.56826729e-01, 5.04551152e-01,
 2.33872321e-01, 3.89804309e-17, -1.55914881e-01,
 -2.16236208e-01, -1.89206682e-01, -1.03943254e-01,
 -3.89804309e-17, 8.50444803e-02, 1.26137788e-01,
 1.16434881e-01, 6.68206631e-02, 3.89804309e-17,
 -5.84680802e-02, -8.90384387e-02, -8.40918587e-02,
 -4.92362781e-02, -3.89804309e-17])
```

```

>>> plt.plot(x, np.sinc(x))
[<matplotlib.lines.Line2D object at 0x...>]
>>> plt.title("Sinc Function")
Text(0.5, 1.0, 'Sinc Function')
>>> plt.ylabel("Amplitude")
Text(0, 0.5, 'Amplitude')
>>> plt.xlabel("X")
Text(0.5, 0, 'X')
>>> plt.show()

```

It works in 2-D as well:

```

>>> x = np.linspace(-4, 4, 401)
>>> xx = np.outer(x, x)
>>> plt.imshow(np.sinc(xx))
<matplotlib.image.AxesImage object at 0x...>

```

## 6.28 Statistical functions (`scipy.stats`)

This module contains a large number of probability distributions as well as a growing library of statistical functions.

Each univariate distribution is an instance of a subclass of `rv_continuous` (`rv_discrete` for discrete distributions):

<code>rv_continuous</code> ([momtype, a, b, xtol, ...])	A generic continuous random variable class meant for subclassing.
<code>rv_discrete</code> ([a, b, name, badvalue, ...])	A generic discrete random variable class meant for subclassing.
<code>rv_histogram</code> (histogram, *args, **kwargs)	Generates a distribution given by a histogram.

### 6.28.1 `scipy.stats.rv_continuous`

**class** `scipy.stats.rv_continuous` (*momtype=1, a=None, b=None, xtol=1e-14, badvalue=None, name=None, longname=None, shapes=None, extradoc=None, seed=None*)

A generic continuous random variable class meant for subclassing.

`rv_continuous` is a base class to construct specific distribution classes and instances for continuous random variables. It cannot be used directly as a distribution.

#### *Parameters*

<b>momtype</b>	[int, optional] The type of generic moment calculation to use: 0 for pdf, 1 (default) for ppf.
<b>a</b>	[float, optional] Lower bound of the support of the distribution, default is minus infinity.
<b>b</b>	[float, optional] Upper bound of the support of the distribution, default is plus infinity.
<b>xtol</b>	[float, optional] The tolerance for fixed point calculation for generic ppf.
<b>badvalue</b>	[float, optional] The value in a result arrays that indicates a value that for which some argument restriction is violated, default is <code>np.nan</code> .
<b>name</b>	[str, optional] The name of the instance. This string is used to construct the default example for distributions.
<b>longname</b>	[str, optional] This string is used as part of the first line of the docstring returned when a subclass has no docstring of its own. Note: <code>longname</code> exists for backwards compatibility, do not use for new subclasses.
<b>shapes</b>	[str, optional] The shape of the distribution. For example "m, n" for a distribution that takes two integers as the two shape arguments for all its methods. If not provided, shape parameters will be inferred from the signature of the private methods, <code>_pdf</code> and <code>_cdf</code> of the instance.
<b>extradoc</b>	[str, optional, deprecated] This string is used as the last part of the docstring returned when a subclass has no docstring of its own. Note: <code>extradoc</code> exists for backwards compatibility, do not use for new subclasses.
<b>seed</b>	[None or int or <code>numpy.random.RandomState</code> instance, optional] This parameter defines the <code>RandomState</code> object to use for drawing random variates. If None (or <code>np.random</code> ), the global <code>np.random</code> state is used. If integer, it is used to seed the local <code>RandomState</code> instance. Default is None.

## Notes

Public methods of an instance of a distribution class (e.g., `pdf`, `cdf`) check their arguments and pass valid arguments to private, computational methods (`_pdf`, `_cdf`). For `pdf(x)`, `x` is valid if it is within the support of the distribution. Whether a shape parameter is valid is decided by an `_argcheck` method (which defaults to checking that its arguments are strictly positive.)

## Subclassing

New random variables can be defined by subclassing the `rv_continuous` class and re-defining at least the `_pdf` or the `_cdf` method (normalized to location 0 and scale 1).

If positive argument checking is not correct for your RV then you will also need to re-define the `_argcheck` method.

For most of the `scipy.stats` distributions, the support interval doesn't depend on the shape parameters. `x` being in the support interval is equivalent to `self.a <= x <= self.b`. If either of the endpoints of the support do depend on the shape parameters, then i) the distribution must implement the `_get_support` method; and ii) those dependent endpoints must be omitted from the distribution's call to the `rv_continuous` initializer.

Correct, but potentially slow defaults exist for the remaining methods but for speed and/or accuracy you can override:

```
_logpdf, _cdf, _logcdf, _ppf, _rvs, _isf, _sf, _logsf
```

The default method `_rvs` relies on the inverse of the cdf, `_ppf`, applied to a uniform random variate. In order to generate random variates efficiently, either the default `_ppf` needs to be overwritten (e.g. if the inverse cdf can be expressed in an explicit form) or a sampling method needs to be implemented in a custom `_rvs` method.

If possible, you should override `_isf`, `_sf` or `_logsf`. The main reason would be to improve numerical accuracy: for example, the survival function `_sf` is computed as `1 - _cdf` which can result in loss of precision if `_cdf(x)` is close to one.

## Methods that can be overwritten by subclasses

```
_rvs
_pdf
_cdf
_sf
_ppf
_isf
_stats
_munp
_entropy
_argcheck
_get_support
```

There are additional (internal and private) generic methods that can be useful for cross-checking and for debugging, but might work in all cases when directly called.

A note on `shapes`: subclasses need not specify them explicitly. In this case, `shapes` will be automatically deduced from the signatures of the overridden methods (`pdf`, `cdf` etc). If, for some reason, you prefer to avoid relying on introspection, you can specify `shapes` explicitly as an argument to the instance constructor.

## Frozen Distributions

Normally, you must provide shape parameters (and, optionally, location and scale parameters to each call of a method of a distribution.

Alternatively, the object may be called (as a function) to fix the shape, location, and scale parameters returning a “frozen” continuous RV object:

`rv = generic(<shape(s)>, loc=0, scale=1)`

`rv_frozen` object with the same methods but holding the given shape, location, and scale fixed

### Statistics

Statistics are computed using numerical integration by default. For speed you can redefine this using `_stats`:

- take shape parameters and return mu, mu2, g1, g2
- If you can’t compute one of these, return it as None
- Can also be defined with a keyword argument `moments`, which is a string composed of “m”, “v”, “s”, and/or “k”. Only the components appearing in string should be computed and returned in the order “m”, “v”, “s”, or “k” with missing values returned as None.

Alternatively, you can override `_munp`, which takes `n` and shape parameters and returns the `n`-th non-central moment of the distribution.

### Examples

To create a new Gaussian distribution, we would do the following:

```
>>> from scipy.stats import rv_continuous
>>> class gaussian_gen(rv_continuous):
... "Gaussian distribution"
... def _pdf(self, x):
... return np.exp(-x**2 / 2.) / np.sqrt(2.0 * np.pi)
>>> gaussian = gaussian_gen(name='gaussian')
```

`scipy.stats` distributions are *instances*, so here we subclass `rv_continuous` and create an instance. With this, we now have a fully functional distribution with all relevant methods automatically generated by the framework.

Note that above we defined a standard normal distribution, with zero mean and unit variance. Shifting and scaling of the distribution can be done by using `loc` and `scale` parameters: `gaussian.pdf(x, loc, scale)` essentially computes  $y = (x - loc) / scale$  and `gaussian._pdf(y) / scale`.

#### Attributes

##### `random_state`

Get or set the RandomState object for generating random variates.

### Methods

<code>rvs(*args, **kwargs)</code>	Random variates of given type.
<code>pdf(x, *args, **kwargs)</code>	Probability density function at <code>x</code> of the given RV.
<code>logpdf(x, *args, **kwargs)</code>	Log of the probability density function at <code>x</code> of the given RV.
<code>cdf(x, *args, **kwargs)</code>	Cumulative distribution function of the given RV.
<code>logcdf(x, *args, **kwargs)</code>	Log of the cumulative distribution function at <code>x</code> of the given RV.
<code>sf(x, *args, **kwargs)</code>	Survival function ( $1 - cdf$ ) at <code>x</code> of the given RV.
<code>logsf(x, *args, **kwargs)</code>	Log of the survival function of the given RV.

Continued on next page

Table 249 – continued from previous page

<code>ppf(q, *args, **kwargs)</code>	Percent point function (inverse of <code>cdf</code> ) at <code>q</code> of the given RV.
<code>isf(q, *args, **kwargs)</code>	Inverse survival function (inverse of <code>sf</code> ) at <code>q</code> of the given RV.
<code>moment(n, *args, **kwargs)</code>	<code>n</code> -th order non-central moment of distribution.
<code>stats(*args, **kwargs)</code>	Some statistics of the given RV.
<code>entropy(*args, **kwargs)</code>	Differential entropy of the RV.
<code>expect([func, args, loc, scale, lb, ub, ...])</code>	Calculate expected value of a function with respect to the distribution by numerical integration.
<code>median(*args, **kwargs)</code>	Median of the distribution.
<code>mean(*args, **kwargs)</code>	Mean of the distribution.
<code>std(*args, **kwargs)</code>	Standard deviation of the distribution.
<code>var(*args, **kwargs)</code>	Variance of the distribution.
<code>interval(alpha, *args, **kwargs)</code>	Confidence interval with equal areas around the median.
<code>__call__(*args, **kwargs)</code>	Freeze the distribution for the given arguments.
<code>fit(data, *args, **kwargs)</code>	Return MLEs for shape (if applicable), location, and scale parameters from data.
<code>fit_loc_scale(data, *args)</code>	Estimate loc and scale parameters from data using 1st and 2nd moments.
<code>nllf(theta, x)</code>	Return negative loglikelihood function.
<code>support(*args, **kwargs)</code>	Return the support of the distribution.

**scipy.stats.rv\_continuous.rvs**

`rv_continuous.rvs(*args, **kwargs)`

Random variates of given type.

**Parameters**

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] Location parameter (default=0).

**scale** [array\_like, optional] Scale parameter (default=1).

**size** [int or tuple of ints, optional] Defining number of random variates (default is 1).

**random\_state**

[None or int or `np.random.RandomState` instance, optional] If int or `RandomState`, use it for drawing the random variates. If None, rely on `self.random_state`. Default is None.

**Returns**

**rvs** [ndarray or scalar] Random variates of given *size*.

**scipy.stats.rv\_continuous.pdf**

`rv_continuous.pdf(x, *args, **kwargs)`

Probability density function at `x` of the given RV.

**Parameters**

**x** [array\_like] quantiles

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**pdf** [ndarray] Probability density function evaluated at x

**scipy.stats.rv\_continuous.logpdf**

`rv_continuous.logpdf(x, *args, **kwargs)`

Log of the probability density function at x of the given RV.

This uses a more numerically accurate calculation if available.

**Parameters**

**x** [array\_like] quantiles

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**logpdf** [array\_like] Log of the probability density function evaluated at x

**scipy.stats.rv\_continuous.cdf**

`rv_continuous.cdf(x, *args, **kwargs)`

Cumulative distribution function of the given RV.

**Parameters**

**x** [array\_like] quantiles

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**cdf** [ndarray] Cumulative distribution function evaluated at x

**scipy.stats.rv\_continuous.logcdf**

`rv_continuous.logcdf(x, *args, **kwargs)`

Log of the cumulative distribution function at x of the given RV.

**Parameters**

**x** [array\_like] quantiles

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**logcdf** [array\_like] Log of the cumulative distribution function evaluated at  $x$

**scipy.stats.rv\_continuous.sf**

`rv_continuous.sf(x, *args, **kws)`  
 Survival function (1 - *cdf*) at  $x$  of the given RV.

**Parameters**

**x** [array\_like] quantiles

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**sf** [array\_like] Survival function evaluated at  $x$

**scipy.stats.rv\_continuous.logsf**

`rv_continuous.logsf(x, *args, **kws)`  
 Log of the survival function of the given RV.  
 Returns the log of the “survival function,” defined as (1 - *cdf*), evaluated at  $x$ .

**Parameters**

**x** [array\_like] quantiles

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**logsf** [ndarray] Log of the survival function evaluated at  $x$ .

**scipy.stats.rv\_continuous.ppf**

`rv_continuous.ppf(q, *args, **kws)`  
 Percent point function (inverse of *cdf*) at  $q$  of the given RV.

**Parameters**

**q** [array\_like] lower tail probability

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**x** [array\_like] quantile corresponding to the lower tail probability  $q$ .

**scipy.stats.rv\_continuous.isf**

`rv_continuous.isf(q, *args, **kwargs)`  
 Inverse survival function (inverse of  $sf$ ) at  $q$  of the given RV.

**Parameters**

**q** [array\_like] upper tail probability

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**x** [ndarray or scalar] Quantile corresponding to the upper tail probability  $q$ .

**scipy.stats.rv\_continuous.moment**

`rv_continuous.moment(n, *args, **kwargs)`  
 $n$ -th order non-central moment of distribution.

**Parameters**

**n** [int,  $n \geq 1$ ] Order of moment.

**arg1, arg2, arg3,...**  
 [float] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

**scipy.stats.rv\_continuous.stats**

`rv_continuous.stats(*args, **kwargs)`  
 Some statistics of the given RV.

**Parameters**

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional (continuous RVs only)] scale parameter (default=1)

**moments** [str, optional] composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's) kurtosis. (default is 'mv')

**Returns**

**stats** [sequence] of requested moments.

**scipy.stats.rv\_continuous.entropy**

`rv_continuous.entropy(*args, **kws)`

Differential entropy of the RV.

**Parameters**

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] Location parameter (default=0).

**scale** [array\_like, optional (continuous distributions only).] Scale parameter (default=1).

**Notes**

Entropy is defined base  $e$ :

```
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

**scipy.stats.rv\_continuous.expect**

`rv_continuous.expect(func=None, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)`

Calculate expected value of a function with respect to the distribution by numerical integration.

The expected value of a function  $f(x)$  with respect to a distribution `dist` is defined as:

$$E[f(x)] = \int_{lb}^{ub} f(x) * dist.pdf(x),$$

where `ub` and `lb` are arguments and `x` has the `dist.pdf(x)` distribution. If the bounds `lb` and `ub` correspond to the support of the distribution, e.g. `[-inf, inf]` in the default case, then the integral is the unrestricted expectation of  $f(x)$ . Also, the function  $f(x)$  may be defined such that  $f(x)$  is 0 outside a finite interval in which case the expectation is calculated within the finite range `[lb, ub]`.

**Parameters**

**func** [callable, optional] Function for which integral is calculated. Takes only one argument. The default is the identity mapping  $f(x) = x$ .

**args** [tuple, optional] Shape parameters of the distribution.

**loc** [float, optional] Location parameter (default=0).

**scale** [float, optional] Scale parameter (default=1).

**lb, ub** [scalar, optional] Lower and upper bound for integration. Default is set to the support of the distribution.

**conditional**

[bool, optional] If True, the integral is corrected by the conditional probability of the integration interval. The return value is the expectation of the function, conditional on being in the given interval. Default is False.

Additional keyword arguments are passed to the integration routine.

**Returns**

**expect** [float] The calculated expected value.

**Notes**

The integration behavior of this function is inherited from `scipy.integrate.quad`. Neither this function nor `scipy.integrate.quad` can verify whether the integral exists or is finite. For example `cauchy(0).mean()` returns `np.nan` and `cauchy(0).expect()` returns `0.0`.

**Examples**

To understand the effect of the bounds of integration consider `>>> from scipy.stats import expon >>> expon(1).expect(lambda x: 1, lb=0.0, ub=2.0)` `0.6321205588285578`

This is close to

```
>>> expon(1).cdf(2.0) - expon(1).cdf(0.0)
0.6321205588285577
```

If `conditional=True`

```
>>> expon(1).expect(lambda x: 1, lb=0.0, ub=2.0, conditional=True)
1.0000000000000002
```

The slight deviation from 1 is due to numerical integration.

**scipy.stats.rv\_continuous.median**

`rv_continuous.median(*args, **kws)`

Median of the distribution.

**Parameters**

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] Location parameter, Default is 0.

**scale** [array\_like, optional] Scale parameter, Default is 1.

**Returns**

**median** [float] The median of the distribution.

See also:

[rv\\_discrete.ppf](#)

Inverse of the CDF

**scipy.stats.rv\_continuous.mean**

`rv_continuous.mean` (*\*args, \*\*kwargs*)

Mean of the distribution.

*Parameters*

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

*Returns*

**mean** [float] the mean of the distribution

**scipy.stats.rv\_continuous.std**

`rv_continuous.std` (*\*args, \*\*kwargs*)

Standard deviation of the distribution.

*Parameters*

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

*Returns*

**std** [float] standard deviation of the distribution

**scipy.stats.rv\_continuous.var**

`rv_continuous.var` (*\*args, \*\*kwargs*)

Variance of the distribution.

*Parameters*

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

*Returns*

**var** [float] the variance of the distribution

**scipy.stats.rv\_continuous.interval**

`rv_continuous.interval` (*alpha, \*args, \*\*kwargs*)

Confidence interval with equal areas around the median.

*Parameters*

**alpha** [array\_like of float] Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].

**arg1, arg2, ...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] location parameter, Default is 0.

**scale** [array\_like, optional] scale parameter, Default is 1.

**Returns**

**a, b** [ndarray of float] end-points of range that contain  $100 * \alpha$  % of the rv's possible values.

**scipy.stats.rv\_continuous.\_\_call\_\_**

`rv_continuous.__call__(*args, **kwargs)`

Freeze the distribution for the given arguments.

**Parameters**

**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

**Returns**

**rv\_frozen** [rv\_frozen instance] The frozen distribution.

**scipy.stats.rv\_continuous.fit**

`rv_continuous.fit(data, *args, **kwargs)`

Return MLEs for shape (if applicable), location, and scale parameters from data.

MLE stands for Maximum Likelihood Estimate. Starting estimates for the fit are given by input arguments; for any arguments not provided with starting estimates, `self._fitstart(data)` is called to generate such.

One can hold some parameters fixed to specific values by passing in keyword arguments `f0, f1, ..., fn` (for shape parameters) and `floc` and `fscale` (for location and scale parameters, respectively).

**Parameters**

**data** [array\_like] Data to use in calculating the MLEs.

**args** [floats, optional] Starting value(s) for any shape-characterizing arguments (those not provided will be determined by a call to `_fitstart(data)`). No default value.

**kwargs** [floats, optional] Starting values for the location and scale parameters; no default. Special keyword arguments are recognized as holding certain parameters fixed:

- `f0...fn` : hold respective shape parameters fixed. Alternatively, shape parameters to fix can be specified by name. For example, if `self.shapes == "a, b"`, `fa` and ``fix_a` are equivalent to `f0`, and `fb` and `fix_b` are equivalent to `f1`.
- `floc` : hold location parameter fixed to specified value.
- `fscale` : hold scale parameter fixed to specified value.
- `optimizer` : The optimizer to use. The optimizer must take `func`, and starting position as the first two arguments, plus `args` (for extra arguments to pass to the function to be optimized) and `disp=0` to suppress output as keyword arguments.

**Returns**

**mle\_tuple** [tuple of floats] MLEs for any shape parameters (if applicable), followed by those for location and scale. For most random variables, shape statistics will be returned, but there are exceptions (e.g. `norm`).

## Notes

This fit is computed by maximizing a log-likelihood function, with penalty applied for samples outside of range of the distribution. The returned answer is not guaranteed to be the globally optimal MLE, it may only be locally optimal, or the optimization may fail altogether.

## Examples

Generate some data to fit: draw random variates from the *beta* distribution

```
>>> from scipy.stats import beta
>>> a, b = 1., 2.
>>> x = beta.rvs(a, b, size=1000)
```

Now we can fit all four parameters (a, b, loc and scale):

```
>>> a1, b1, loc1, scale1 = beta.fit(x)
```

We can also use some prior knowledge about the dataset: let's keep loc and scale fixed:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, floc=0, fscale=1)
>>> loc1, scale1
(0, 1)
```

We can also keep shape parameters fixed by using *f*-keywords. To keep the zero-th shape parameter *a* equal 1, use `f0=1` or, equivalently, `fa=1`:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, fa=1, floc=0, fscale=1)
>>> a1
1
```

Not all distributions return estimates for the shape parameters. `norm` for example just returns estimates for location and scale:

```
>>> from scipy.stats import norm
>>> x = norm.rvs(a, b, size=1000, random_state=123)
>>> loc1, scale1 = norm.fit(x)
>>> loc1, scale1
(0.92087172783841631, 2.0015750750324668)
```

## `scipy.stats.rv_continuous.fit_loc_scale`

`rv_continuous.fit_loc_scale` (*data*, \**args*)

Estimate loc and scale parameters from data using 1st and 2nd moments.

### Parameters

**data** [array\_like] Data to fit.

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**Returns**

**Lhat** [float] Estimated location parameter for the data.

**Shat** [float] Estimated scale parameter for the data.

**scipy.stats.rv\_continuous.nnlf**

`rv_continuous.nnlf(theta, x)`

Return negative loglikelihood function.

**Notes**

This is `-sum(log pdf(x, theta), axis=0)` where *theta* are the parameters (including loc and scale).

**scipy.stats.rv\_continuous.support**

`rv_continuous.support(*args, **kwargs)`

Return the support of the distribution.

**Parameters**

**arg1, arg2, ...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] location parameter, Default is 0.

**scale** [array\_like, optional] scale parameter, Default is 1.

**Returns**

**a, b** [float] end-points of the distribution's support.

**6.28.2 scipy.stats.rv\_discrete**

**class** `scipy.stats.rv_discrete` (*a=0, b=inf, name=None, badvalue=None, moment\_tol=1e-08, values=None, inc=1, longname=None, shapes=None, extradoc=None, seed=None*)

A generic discrete random variable class meant for subclassing.

`rv_discrete` is a base class to construct specific distribution classes and instances for discrete random variables. It can also be used to construct an arbitrary distribution defined by a list of support points and corresponding probabilities.

**Parameters**

**a** [float, optional] Lower bound of the support of the distribution, default: 0

**b** [float, optional] Upper bound of the support of the distribution, default: plus infinity

**moment\_tol** [float, optional] The tolerance for the generic calculation of moments.

<b>values</b>	[tuple of two array_like, optional] ( $x_k, p_k$ ) where $x_k$ are integers and $p_k$ are the non-zero probabilities between 0 and 1 with $\sum(p_k) = 1$ . $x_k$ and $p_k$ must have the same shape.
<b>inc</b>	[integer, optional] Increment for the support of the distribution. Default is 1. (other values have not been tested)
<b>badvalue</b>	[float, optional] The value in a result arrays that indicates a value that for which some argument restriction is violated, default is <code>np.nan</code> .
<b>name</b>	[str, optional] The name of the instance. This string is used to construct the default example for distributions.
<b>longname</b>	[str, optional] This string is used as part of the first line of the docstring returned when a subclass has no docstring of its own. Note: <i>longname</i> exists for backwards compatibility, do not use for new subclasses.
<b>shapes</b>	[str, optional] The shape of the distribution. For example "m, n" for a distribution that takes two integers as the two shape arguments for all its methods. If not provided, shape parameters will be inferred from the signatures of the private methods, <code>_pmf</code> and <code>_cdf</code> of the instance.
<b>extradoc</b>	[str, optional] This string is used as the last part of the docstring returned when a subclass has no docstring of its own. Note: <i>extradoc</i> exists for backwards compatibility, do not use for new subclasses.
<b>seed</b>	[None or int or <code>numpy.random.RandomState</code> instance, optional] This parameter defines the <code>RandomState</code> object to use for drawing random variates. If <code>None</code> , the global <code>np.random</code> state is used. If integer, it is used to seed the local <code>RandomState</code> instance. Default is <code>None</code> .

## Notes

This class is similar to *rv\_continuous*. Whether a shape parameter is valid is decided by an `_argcheck` method (which defaults to checking that its arguments are strictly positive.) The main differences are:

- the support of the distribution is a set of integers
- instead of the probability density function, `pdf` (and the corresponding private `_pdf`), this class defines the *probability mass function*, `pmf` (and the corresponding private `_pmf`.)
- scale parameter is not defined.

To create a new discrete distribution, we would do the following:

```
>>> from scipy.stats import rv_discrete
>>> class poisson_gen(rv_discrete):
... "Poisson distribution"
... def _pmf(self, k, mu):
... return exp(-mu) * mu**k / factorial(k)
```

and create an instance:

```
>>> poisson = poisson_gen(name="poisson")
```

Note that above we defined the Poisson distribution in the standard form. Shifting the distribution can be done by providing the `loc` parameter to the methods of the instance. For example, `poisson.pmf(x, mu, loc)` delegates the work to `poisson._pmf(x-loc, mu)`.

### Discrete distributions from a list of probabilities

Alternatively, you can construct an arbitrary discrete rv defined on a finite set of values  $x_k$  with  $\text{Prob}\{X=x_k\} = p_k$  by using the `values` keyword argument to the *rv\_discrete* constructor.

## Examples

Custom made discrete distribution:

```
>>> from scipy import stats
>>> xk = np.arange(7)
>>> pk = (0.1, 0.2, 0.3, 0.1, 0.1, 0.0, 0.2)
>>> custm = stats.rv_discrete(name='custm', values=(xk, pk))
>>>
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
>>> ax.plot(xk, custm.pmf(xk), 'ro', ms=12, mec='r')
>>> ax.vlines(xk, 0, custm.pmf(xk), colors='r', lw=4)
>>> plt.show()
```

Random number generation:

```
>>> R = custm.rvs(size=100)
```

### Attributes

#### **random\_state**

Get or set the RandomState object for generating random variates.

### Methods

<i>rvs</i> (*args, **kwargs)	Random variates of given type.
<i>pmf</i> (k, *args, **kwargs)	Probability mass function at k of the given RV.
<i>logpmf</i> (k, *args, **kwargs)	Log of the probability mass function at k of the given RV.
<i>cdf</i> (k, *args, **kwargs)	Cumulative distribution function of the given RV.

Continued on next page

Table 250 – continued from previous page

<code>logcdf(k, *args, **kwargs)</code>	Log of the cumulative distribution function at $k$ of the given RV.
<code>sf(k, *args, **kwargs)</code>	Survival function ( $1 - cdf$ ) at $k$ of the given RV.
<code>logsf(k, *args, **kwargs)</code>	Log of the survival function of the given RV.
<code>ppf(q, *args, **kwargs)</code>	Percent point function (inverse of $cdf$ ) at $q$ of the given RV.
<code>isf(q, *args, **kwargs)</code>	Inverse survival function (inverse of $sf$ ) at $q$ of the given RV.
<code>moment(n, *args, **kwargs)</code>	$n$ -th order non-central moment of distribution.
<code>stats(*args, **kwargs)</code>	Some statistics of the given RV.
<code>entropy(*args, **kwargs)</code>	Differential entropy of the RV.
<code>expect([func, args, loc, lb, ub, ...])</code>	Calculate expected value of a function with respect to the distribution for discrete distribution by numerical summation.
<code>median(*args, **kwargs)</code>	Median of the distribution.
<code>mean(*args, **kwargs)</code>	Mean of the distribution.
<code>std(*args, **kwargs)</code>	Standard deviation of the distribution.
<code>var(*args, **kwargs)</code>	Variance of the distribution.
<code>interval(alpha, *args, **kwargs)</code>	Confidence interval with equal areas around the median.
<code>__call__(*args, **kwargs)</code>	Freeze the distribution for the given arguments.
<code>support(*args, **kwargs)</code>	Return the support of the distribution.

**scipy.stats.rv\_discrete.rvs**

`rv_discrete.rvs (*args, **kwargs)`

Random variates of given type.

**Parameters**

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] Location parameter (default=0).

**size** [int or tuple of ints, optional] Defining number of random variates (Default is 1). Note that *size* has to be given as keyword, not as positional argument.

**random\_state**

[None or int or `np.random.RandomState` instance, optional] If int or `RandomState`, use it for drawing the random variates. If None, rely on `self.random_state`. Default is None.

**Returns**

**rvs** [ndarray or scalar] Random variates of given *size*.

**scipy.stats.rv\_discrete.pmf**

`rv_discrete.pmf (k, *args, **kwargs)`

Probability mass function at  $k$  of the given RV.

**Parameters**

**k** [array\_like] Quantiles.

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] Location parameter (default=0).

**Returns**

**pmf** [array\_like] Probability mass function evaluated at k

**scipy.stats.rv\_discrete.logpmf**

`rv_discrete.logpmf(k, *args, **kws)`

Log of the probability mass function at k of the given RV.

**Parameters**

**k** [array\_like] Quantiles.

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] Location parameter. Default is 0.

**Returns**

**logpmf** [array\_like] Log of the probability mass function evaluated at k.

**scipy.stats.rv\_discrete.cdf**

`rv_discrete.cdf(k, *args, **kws)`

Cumulative distribution function of the given RV.

**Parameters**

**k** [array\_like, int] Quantiles.

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] Location parameter (default=0).

**Returns**

**cdf** [ndarray] Cumulative distribution function evaluated at k.

**scipy.stats.rv\_discrete.logcdf**

`rv_discrete.logcdf(k, *args, **kws)`

Log of the cumulative distribution function at k of the given RV.

**Parameters**

**k** [array\_like, int] Quantiles.

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] Location parameter (default=0).

**Returns**

**logcdf** [array\_like] Log of the cumulative distribution function evaluated at k.

**scipy.stats.rv\_discrete.sf**

`rv_discrete.sf` (*k*, \*args, \*\*kwargs)  
Survival function ( $1 - cdf$ ) at *k* of the given RV.

**Parameters**

**k** [array\_like] Quantiles.  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] Location parameter (default=0).

**Returns**

**sf** [array\_like] Survival function evaluated at *k*.

**scipy.stats.rv\_discrete.logsf**

`rv_discrete.logsf` (*k*, \*args, \*\*kwargs)  
Log of the survival function of the given RV.  
Returns the log of the “survival function,” defined as  $1 - cdf$ , evaluated at *k*.

**Parameters**

**k** [array\_like] Quantiles.  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] Location parameter (default=0).

**Returns**

**logsf** [ndarray] Log of the survival function evaluated at *k*.

**scipy.stats.rv\_discrete.ppf**

`rv_discrete.ppf` (*q*, \*args, \*\*kwargs)  
Percent point function (inverse of  $cdf$ ) at *q* of the given RV.

**Parameters**

**q** [array\_like] Lower tail probability.  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] Location parameter (default=0).

**Returns**

**k** [array\_like] Quantile corresponding to the lower tail probability, *q*.

**scipy.stats.rv\_discrete.isf**`rv_discrete.isf` (*q*, \**args*, \*\**kwds*)Inverse survival function (inverse of *sf*) at *q* of the given RV.**Parameters**

**q** [array\_like] Upper tail probability.  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] Location parameter (default=0).

**Returns****k** [ndarray or scalar] Quantile corresponding to the upper tail probability, *q*.**scipy.stats.rv\_discrete.moment**`rv_discrete.moment` (*n*, \**args*, \*\**kwds*)*n*-th order non-central moment of distribution.**Parameters**

**n** [int, *n* >= 1] Order of moment.  
**arg1, arg2, arg3,...** [float] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**scipy.stats.rv\_discrete.stats**`rv_discrete.stats` (\**args*, \*\**kwds*)

Some statistics of the given RV.

**Parameters**

**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional (continuous RVs only)] scale parameter (default=1)  
**moments** [str, optional] composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's) kurtosis. (default is 'mv')

**Returns****stats** [sequence] of requested moments.**scipy.stats.rv\_discrete.entropy**`rv_discrete.entropy` (\**args*, \*\**kwds*)

Differential entropy of the RV.

**Parameters**

**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] Location parameter (default=0).

**scale** [array\_like, optional (continuous distributions only).] Scale parameter (default=1).

## Notes

Entropy is defined base  $e$ :

```
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

## scipy.stats.rv\_discrete.expect

`rv_discrete.expect` (*func=None, args=(), loc=0, lb=None, ub=None, conditional=False, maxcount=1000, tolerance=1e-10, chunksize=32*)

Calculate expected value of a function with respect to the distribution for discrete distribution by numerical summation.

### Parameters

**func** [callable, optional] Function for which the expectation value is calculated. Takes only one argument. The default is the identity mapping  $f(k) = k$ .

**args** [tuple, optional] Shape parameters of the distribution.

**loc** [float, optional] Location parameter. Default is 0.

**lb, ub** [int, optional] Lower and upper bound for the summation, default is set to the support of the distribution, inclusive ( $ub \leq k \leq lb$ ).

**conditional** [bool, optional] If true then the expectation is corrected by the conditional probability of the summation interval. The return value is the expectation of the function, *func*, conditional on being in the given interval ( $k$  such that  $ub \leq k \leq lb$ ). Default is False.

**maxcount** [int, optional] Maximal number of terms to evaluate (to avoid an endless loop for an infinite sum). Default is 1000.

**tolerance** [float, optional] Absolute tolerance for the summation. Default is  $1e-10$ .

**chunksize** [int, optional] Iterate over the support of a distributions in chunks of this size. Default is 32.

### Returns

**expect** [float] Expected value.

## Notes

For heavy-tailed distributions, the expected value may or may not exist, depending on the function, *func*. If it does exist, but the sum converges slowly, the accuracy of the result may be rather low. For instance, for `zipf(4)`, accuracy for mean, variance in example is only  $1e-5$ . increasing *maxcount* and/or *chunksize* may improve the result, but may also make zipf very slow.

The function is not vectorized.

### scipy.stats.rv\_discrete.median

`rv_discrete.median` (\*args, \*\*kwargs)

Median of the distribution.

#### Parameters

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] Location parameter, Default is 0.

**scale** [array\_like, optional] Scale parameter, Default is 1.

#### Returns

**median** [float] The median of the distribution.

See also:

`rv_discrete.ppf`

Inverse of the CDF

### scipy.stats.rv\_discrete.mean

`rv_discrete.mean` (\*args, \*\*kwargs)

Mean of the distribution.

#### Parameters

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

#### Returns

**mean** [float] the mean of the distribution

### scipy.stats.rv\_discrete.std

`rv_discrete.std` (\*args, \*\*kwargs)

Standard deviation of the distribution.

#### Parameters

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

#### Returns

**std** [float] standard deviation of the distribution

**scipy.stats.rv\_discrete.var**

`rv_discrete.var` (*\*args, \*\*kwargs*)

Variance of the distribution.

*Parameters*

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

*Returns*

**var** [float] the variance of the distribution

**scipy.stats.rv\_discrete.interval**

`rv_discrete.interval` (*alpha, \*args, \*\*kwargs*)

Confidence interval with equal areas around the median.

*Parameters*

**alpha** [array\_like of float] Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].

**arg1, arg2, ...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] location parameter, Default is 0.

**scale** [array\_like, optional] scale parameter, Default is 1.

*Returns*

**a, b** [ndarray of float] end-points of range that contain  $100 * \alpha$  % of the rv's possible values.

**scipy.stats.rv\_discrete.\_\_call\_\_**

`rv_discrete.__call__` (*\*args, \*\*kwargs*)

Freeze the distribution for the given arguments.

*Parameters*

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

*Returns*

**rv\_frozen** [rv\_frozen instance] The frozen distribution.

**scipy.stats.rv\_discrete.support**

`rv_discrete.support(*args, **kwargs)`

Return the support of the distribution.

*Parameters*

**arg1, arg2, ...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] location parameter, Default is 0.

**scale** [array\_like, optional] scale parameter, Default is 1.

**Returns**

**a, b** [float] end-points of the distribution's support.

**6.28.3 scipy.stats.rv\_histogram**

**class** `scipy.stats.rv_histogram` (*histogram*, \*args, \*\*kwargs)

Generates a distribution given by a histogram. This is useful to generate a template distribution from a binned datasample.

As a subclass of the `rv_continuous` class, `rv_histogram` inherits from it a collection of generic methods (see `rv_continuous` for the full list), and implements them based on the properties of the provided binned datasample.

*Parameters*

**histogram** [tuple of array\_like] Tuple containing two array\_like objects The first containing the content of n bins The second containing the (n+1) bin boundaries In particular the return value `np.histogram` is accepted

**Notes**

There are no additional shape parameters except for the loc and scale. The pdf is defined as a stepwise function from the provided histogram The cdf is a linear interpolation of the pdf.

New in version 0.19.0.

**Examples**

Create a `scipy.stats` distribution from a numpy histogram

```
>>> import scipy.stats
>>> import numpy as np
>>> data = scipy.stats.norm.rvs(size=100000, loc=0, scale=1.5, random_
↳ state=123)
>>> hist = np.histogram(data, bins=100)
>>> hist_dist = scipy.stats.rv_histogram(hist)
```

Behaves like an ordinary `scipy rv_continuous` distribution

```
>>> hist_dist.pdf(1.0)
0.20538577847618705
>>> hist_dist.cdf(2.0)
0.90818568543056499
```

PDF is zero above (below) the highest (lowest) bin of the histogram, defined by the max (min) of the original dataset

```
>>> hist_dist.pdf(np.max(data))
0.0
>>> hist_dist.cdf(np.max(data))
1.0
>>> hist_dist.pdf(np.min(data))
7.7591907244498314e-05
>>> hist_dist.cdf(np.min(data))
0.0
```

PDF and CDF follow the histogram

```
>>> import matplotlib.pyplot as plt
>>> X = np.linspace(-5.0, 5.0, 100)
>>> plt.title("PDF from Template")
>>> plt.hist(data, density=True, bins=100)
>>> plt.plot(X, hist_dist.pdf(X), label='PDF')
>>> plt.plot(X, hist_dist.cdf(X), label='CDF')
>>> plt.show()
```

### Attributes

#### **random\_state**

Get or set the RandomState object for generating random variates.

### Methods

<code>__call__(*args, **kwargs)</code>	Freeze the distribution for the given arguments.
<code>cdf(x, *args, **kwargs)</code>	Cumulative distribution function of the given RV.
<code>entropy(*args, **kwargs)</code>	Differential entropy of the RV.
<code>expect([func, args, loc, scale, lb, ub, ...])</code>	Calculate expected value of a function with respect to the distribution by numerical integration.
<code>fit(data, *args, **kwargs)</code>	Return MLEs for shape (if applicable), location, and scale parameters from data.
<code>fit_loc_scale(data, *args)</code>	Estimate loc and scale parameters from data using 1st and 2nd moments.
<code>freeze(*args, **kwargs)</code>	Freeze the distribution for the given arguments.
<code>interval(alpha, *args, **kwargs)</code>	Confidence interval with equal areas around the median.
<code>isf(q, *args, **kwargs)</code>	Inverse survival function (inverse of <i>sf</i> ) at q of the given RV.
<code>logcdf(x, *args, **kwargs)</code>	Log of the cumulative distribution function at x of the given RV.
<code>logpdf(x, *args, **kwargs)</code>	Log of the probability density function at x of the given RV.
<code>logsf(x, *args, **kwargs)</code>	Log of the survival function of the given RV.
<code>mean(*args, **kwargs)</code>	Mean of the distribution.
<code>median(*args, **kwargs)</code>	Median of the distribution.
<code>moment(n, *args, **kwargs)</code>	n-th order non-central moment of distribution.
<code>nnlf(theta, x)</code>	Return negative loglikelihood function.
<code>pdf(x, *args, **kwargs)</code>	Probability density function at x of the given RV.
<code>ppf(q, *args, **kwargs)</code>	Percent point function (inverse of <i>cdf</i> ) at q of the given RV.
<code>rvs(*args, **kwargs)</code>	Random variates of given type.
<code>sf(x, *args, **kwargs)</code>	Survival function (1 - <i>cdf</i> ) at x of the given RV.
<code>stats(*args, **kwargs)</code>	Some statistics of the given RV.
<code>std(*args, **kwargs)</code>	Standard deviation of the distribution.
<code>support(*args, **kwargs)</code>	Return the support of the distribution.
<code>var(*args, **kwargs)</code>	Variance of the distribution.

### scipy.stats.rv\_histogram.\_\_call\_\_

`rv_histogram.__call__(*args, **kwargs)`  
 Freeze the distribution for the given arguments.

#### Parameters

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

#### Returns

**rv\_frozen** [rv\_frozen instance] The frozen distribution.

### scipy.stats.rv\_histogram.cdf

`rv_histogram.cdf(x, *args, **kwargs)`  
 Cumulative distribution function of the given RV.

#### Parameters

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**cdf** [ndarray] Cumulative distribution function evaluated at  $x$

**scipy.stats.rv\_histogram.entropy**

`rv_histogram.entropy(*args, **kws)`  
 Differential entropy of the RV.

**Parameters**

**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] Location parameter (default=0).  
**scale** [array\_like, optional (continuous distributions only).] Scale parameter (default=1).

**Notes**

Entropy is defined base  $e$ :

```
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

**scipy.stats.rv\_histogram.expect**

`rv_histogram.expect(func=None, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)`

Calculate expected value of a function with respect to the distribution by numerical integration.

The expected value of a function  $f(x)$  with respect to a distribution `dist` is defined as:

$$E[f(x)] = \int_{lb}^{ub} f(x) * dist.pdf(x),$$

where `ub` and `lb` are arguments and `x` has the `dist.pdf(x)` distribution. If the bounds `lb` and `ub` correspond to the support of the distribution, e.g. `[-inf, inf]` in the default case, then the integral is the unrestricted expectation of  $f(x)$ . Also, the function  $f(x)$  may be defined such that  $f(x)$  is 0 outside a finite interval in which case the expectation is calculated within the finite range `[lb, ub]`.

**Parameters**

**func** [callable, optional] Function for which integral is calculated. Takes only one argument. The default is the identity mapping  $f(x) = x$ .  
**args** [tuple, optional] Shape parameters of the distribution.  
**loc** [float, optional] Location parameter (default=0).

**scale** [float, optional] Scale parameter (default=1).  
**lb, ub** [scalar, optional] Lower and upper bound for integration. Default is set to the support of the distribution.

**conditional** [bool, optional] If True, the integral is corrected by the conditional probability of the integration interval. The return value is the expectation of the function, conditional on being in the given interval. Default is False.

**Additional keyword arguments are passed to the integration routine.**

*Returns*

**expect** [float] The calculated expected value.

**Notes**

The integration behavior of this function is inherited from `scipy.integrate.quad`. Neither this function nor `scipy.integrate.quad` can verify whether the integral exists or is finite. For example `cauchy(0).mean()` returns `np.nan` and `cauchy(0).expect()` returns `0.0`.

**Examples**

To understand the effect of the bounds of integration consider `>>> from scipy.stats import expon >>> expon(1).expect(lambda x: 1, lb=0.0, ub=2.0)` 0.6321205588285578

This is close to

```
>>> expon(1).cdf(2.0) - expon(1).cdf(0.0)
0.6321205588285577
```

If `conditional=True`

```
>>> expon(1).expect(lambda x: 1, lb=0.0, ub=2.0, conditional=True)
1.0000000000000002
```

The slight deviation from 1 is due to numerical integration.

**scipy.stats.rv\_histogram.fit**

`rv_histogram.fit` (*data*, \**args*, \*\**kwds*)

Return MLEs for shape (if applicable), location, and scale parameters from data.

MLE stands for Maximum Likelihood Estimate. Starting estimates for the fit are given by input arguments; for any arguments not provided with starting estimates, `self._fitstart(data)` is called to generate such.

One can hold some parameters fixed to specific values by passing in keyword arguments `f0`, `f1`, ..., `fn` (for shape parameters) and `floc` and `fscale` (for location and scale parameters, respectively).

*Parameters*

**data** [array\_like] Data to use in calculating the MLEs.  
**args** [floats, optional] Starting value(s) for any shape-characterizing arguments (those not provided will be determined by a call to `_fitstart(data)`). No default value.  
**kwds** [floats, optional] Starting values for the location and scale parameters; no default. Special keyword arguments are recognized as holding certain parameters fixed:

- `f0...fn` : hold respective shape parameters fixed. Alternatively, shape parameters to fix can be specified by name. For example, if `self.shapes == "a, b"`, `fa` and `fix_a` are equivalent to `f0`, and `fb` and `fix_b` are equivalent to `f1`.
- `floc` : hold location parameter fixed to specified value.
- `fscale` : hold scale parameter fixed to specified value.
- `optimizer` : The optimizer to use. The optimizer must take `func`, and starting position as the first two arguments, plus `args` (for extra arguments to pass to the function to be optimized) and `disp=0` to suppress output as keyword arguments.

### Returns

**mle\_tuple** [tuple of floats] MLEs for any shape parameters (if applicable), followed by those for location and scale. For most random variables, shape statistics will be returned, but there are exceptions (e.g. `norm`).

### Notes

This fit is computed by maximizing a log-likelihood function, with penalty applied for samples outside of range of the distribution. The returned answer is not guaranteed to be the globally optimal MLE, it may only be locally optimal, or the optimization may fail altogether.

### Examples

Generate some data to fit: draw random variates from the *beta* distribution

```
>>> from scipy.stats import beta
>>> a, b = 1., 2.
>>> x = beta.rvs(a, b, size=1000)
```

Now we can fit all four parameters (`a`, `b`, `loc` and `scale`):

```
>>> a1, b1, loc1, scale1 = beta.fit(x)
```

We can also use some prior knowledge about the dataset: let's keep `loc` and `scale` fixed:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, floc=0, fscale=1)
>>> loc1, scale1
(0, 1)
```

We can also keep shape parameters fixed by using `f`-keywords. To keep the zero-th shape parameter `a` equal 1, use `f0=1` or, equivalently, `fa=1`:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, fa=1, floc=0, fscale=1)
>>> a1
1
```

Not all distributions return estimates for the shape parameters. `norm` for example just returns estimates for location and scale:

```
>>> from scipy.stats import norm
>>> x = norm.rvs(a, b, size=1000, random_state=123)
>>> loc1, scale1 = norm.fit(x)
```

(continues on next page)

```
>>> loc1, scale1
(0.92087172783841631, 2.0015750750324668)
```

### scipy.stats.rv\_histogram.fit\_loc\_scale

`rv_histogram.fit_loc_scale` (*data*, \**args*)

Estimate loc and scale parameters from data using 1st and 2nd moments.

#### Parameters

**data** [array\_like] Data to fit.  
**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

#### Returns

**Lhat** [float] Estimated location parameter for the data.  
**Shat** [float] Estimated scale parameter for the data.

### scipy.stats.rv\_histogram.freeze

`rv_histogram.freeze` (\**args*, \*\**kws*)

Freeze the distribution for the given arguments.

#### Parameters

**arg1, arg2, arg3,...**  
 [array\_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

#### Returns

**rv\_frozen** [rv\_frozen instance] The frozen distribution.

### scipy.stats.rv\_histogram.interval

`rv_histogram.interval` (*alpha*, \**args*, \*\**kws*)

Confidence interval with equal areas around the median.

#### Parameters

**alpha** [array\_like of float] Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].  
**arg1, arg2, ...**  
 [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] location parameter, Default is 0.  
**scale** [array\_like, optional] scale parameter, Default is 1.

#### Returns

**a, b** [ndarray of float] end-points of range that contain  $100 * \text{alpha} \%$  of the rv's possible values.

**scipy.stats.rv\_histogram.isf**

`rv_histogram.isf` (*q*, \**args*, \*\**kws*)

Inverse survival function (inverse of *sf*) at *q* of the given RV.

**Parameters**

**q** [array\_like] upper tail probability  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**x** [ndarray or scalar] Quantile corresponding to the upper tail probability *q*.

**scipy.stats.rv\_histogram.logcdf**

`rv_histogram.logcdf` (*x*, \**args*, \*\**kws*)

Log of the cumulative distribution function at *x* of the given RV.

**Parameters**

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**logcdf** [array\_like] Log of the cumulative distribution function evaluated at *x*

**scipy.stats.rv\_histogram.logpdf**

`rv_histogram.logpdf` (*x*, \**args*, \*\**kws*)

Log of the probability density function at *x* of the given RV.

This uses a more numerically accurate calculation if available.

**Parameters**

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**logpdf** [array\_like] Log of the probability density function evaluated at *x*

### scipy.stats.rv\_histogram.logsf

`rv_histogram.logsf(x, *args, **kws)`

Log of the survival function of the given RV.

Returns the log of the “survival function,” defined as  $(1 - cdf)$ , evaluated at  $x$ .

#### Parameters

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

#### Returns

**logsf** [ndarray] Log of the survival function evaluated at  $x$ .

### scipy.stats.rv\_histogram.mean

`rv_histogram.mean(*args, **kws)`

Mean of the distribution.

#### Parameters

**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

#### Returns

**mean** [float] the mean of the distribution

### scipy.stats.rv\_histogram.median

`rv_histogram.median(*args, **kws)`

Median of the distribution.

#### Parameters

**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] Location parameter, Default is 0.  
**scale** [array\_like, optional] Scale parameter, Default is 1.

#### Returns

**median** [float] The median of the distribution.

See also:

[`rv\_discrete.ppf`](#)

Inverse of the CDF

**scipy.stats.rv\_histogram.moment**

`rv_histogram.moment` (*n*, \*args, \*\*kwargs)  
 n-th order non-central moment of distribution.

*Parameters*

**n** [int, n >= 1] Order of moment.  
**arg1, arg2, arg3,...** [float] The shape parameter(s) for the distribution (see docstring of the instance object for more information).  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**scipy.stats.rv\_histogram.nllf**

`rv_histogram.nllf` (*theta*, *x*)  
 Return negative loglikelihood function.

**Notes**

This is  $-\text{sum}(\log \text{pdf}(x, \text{theta}), \text{axis}=0)$  where *theta* are the parameters (including loc and scale).

**scipy.stats.rv\_histogram.pdf**

`rv_histogram.pdf` (*x*, \*args, \*\*kwargs)  
 Probability density function at *x* of the given RV.

*Parameters*

**x** [array\_like] quantiles  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

*Returns*

**pdf** [ndarray] Probability density function evaluated at *x*

**scipy.stats.rv\_histogram.ppf**

`rv_histogram.ppf` (*q*, \*args, \*\*kwargs)  
 Percent point function (inverse of *cdf*) at *q* of the given RV.

*Parameters*

**q** [array\_like] lower tail probability  
**arg1, arg2, arg3,...** [array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)  
**loc** [array\_like, optional] location parameter (default=0)  
**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**x** [array\_like] quantile corresponding to the lower tail probability  $q$ .

**scipy.stats.rv\_histogram.rvs**

`rv_histogram.rvs` (*\*args, \*\*kws*)

Random variates of given type.

**Parameters**

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] Location parameter (default=0).

**scale** [array\_like, optional] Scale parameter (default=1).

**size** [int or tuple of ints, optional] Defining number of random variates (default is 1).

**random\_state**

[None or int or `np.random.RandomState` instance, optional] If int or `RandomState`, use it for drawing the random variates. If None, rely on `self.random_state`. Default is None.

**Returns**

**rvs** [ndarray or scalar] Random variates of given *size*.

**scipy.stats.rv\_histogram.sf**

`rv_histogram.sf` (*x, \*args, \*\*kws*)

Survival function (1 - *cdf*) at *x* of the given RV.

**Parameters**

**x** [array\_like] quantiles

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**sf** [array\_like] Survival function evaluated at *x*

**scipy.stats.rv\_histogram.stats**

`rv_histogram.stats` (*\*args, \*\*kws*)

Some statistics of the given RV.

**Parameters**

**arg1, arg2, arg3,...**

[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional (continuous RVs only)] scale parameter (default=1)

**moments** [str, optional] composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's) kurtosis. (default is 'mv')

**Returns**

**stats** [sequence] of requested moments.

### scipy.stats.rv\_histogram.std

`rv_histogram.std(*args, **kwargs)`  
Standard deviation of the distribution.

**Parameters**

**arg1, arg2, arg3, ...**  
[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**std** [float] standard deviation of the distribution

### scipy.stats.rv\_histogram.support

`rv_histogram.support(*args, **kwargs)`  
Return the support of the distribution.

**Parameters**

**arg1, arg2, ...**  
[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

**loc** [array\_like, optional] location parameter, Default is 0.

**scale** [array\_like, optional] scale parameter, Default is 1.

**Returns**

**a, b** [float] end-points of the distribution's support.

### scipy.stats.rv\_histogram.var

`rv_histogram.var(*args, **kwargs)`  
Variance of the distribution.

**Parameters**

**arg1, arg2, arg3, ...**  
[array\_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

**loc** [array\_like, optional] location parameter (default=0)

**scale** [array\_like, optional] scale parameter (default=1)

**Returns**

**var** [float] the variance of the distribution

## 6.28.4 Continuous distributions

<i>alpha</i>	An alpha continuous random variable.
<i>anglit</i>	An anglit continuous random variable.
<i>arcsine</i>	An arcsine continuous random variable.
<i>argus</i>	Argus distribution
<i>beta</i>	A beta continuous random variable.
<i>betaprime</i>	A beta prime continuous random variable.
<i>bradford</i>	A Bradford continuous random variable.
<i>burr</i>	A Burr (Type III) continuous random variable.
<i>burr12</i>	A Burr (Type XII) continuous random variable.
<i>cauchy</i>	A Cauchy continuous random variable.
<i>chi</i>	A chi continuous random variable.
<i>chi2</i>	A chi-squared continuous random variable.
<i>cosine</i>	A cosine continuous random variable.
<i>crystalball</i>	Crystalball distribution
<i>dgamma</i>	A double gamma continuous random variable.
<i>dweibull</i>	A double Weibull continuous random variable.
<i>erlang</i>	An Erlang continuous random variable.
<i>expon</i>	An exponential continuous random variable.
<i>exponnorm</i>	An exponentially modified Normal continuous random variable.
<i>exponweib</i>	An exponentiated Weibull continuous random variable.
<i>exponpow</i>	An exponential power continuous random variable.
<i>f</i>	An F continuous random variable.
<i>fatiguelife</i>	A fatigue-life (Birnbaum-Saunders) continuous random variable.
<i>fisk</i>	A Fisk continuous random variable.
<i>foldcauchy</i>	A folded Cauchy continuous random variable.
<i>foldnorm</i>	A folded normal continuous random variable.
<i>frechet_r</i>	A Frechet right (or Weibull minimum) continuous random variable.
<i>frechet_l</i>	A Frechet left (or Weibull maximum) continuous random variable.
<i>genlogistic</i>	A generalized logistic continuous random variable.
<i>gennorm</i>	A generalized normal continuous random variable.
<i>genpareto</i>	A generalized Pareto continuous random variable.
<i>genexpon</i>	A generalized exponential continuous random variable.
<i>genextreme</i>	A generalized extreme value continuous random variable.
<i>gausshyper</i>	A Gauss hypergeometric continuous random variable.
<i>gamma</i>	A gamma continuous random variable.
<i>gengamma</i>	A generalized gamma continuous random variable.
<i>genhalflogistic</i>	A generalized half-logistic continuous random variable.
<i>gilbrat</i>	A Gilbrat continuous random variable.
<i>gompertz</i>	A Gompertz (or truncated Gumbel) continuous random variable.
<i>gumbel_r</i>	A right-skewed Gumbel continuous random variable.
<i>gumbel_l</i>	A left-skewed Gumbel continuous random variable.
<i>halfcauchy</i>	A Half-Cauchy continuous random variable.
<i>halflogistic</i>	A half-logistic continuous random variable.
<i>halfnorm</i>	A half-normal continuous random variable.

Continued on next page

Table 252 – continued from previous page

<i>halfgennorm</i>	The upper half of a generalized normal continuous random variable.
<i>hypsecant</i>	A hyperbolic secant continuous random variable.
<i>invgamma</i>	An inverted gamma continuous random variable.
<i>invgauss</i>	An inverse Gaussian continuous random variable.
<i>invweibull</i>	An inverted Weibull continuous random variable.
<i>johnsonsb</i>	A Johnson SB continuous random variable.
<i>johnsonsu</i>	A Johnson SU continuous random variable.
<i>kappa4</i>	Kappa 4 parameter distribution.
<i>kappa3</i>	Kappa 3 parameter distribution.
<i>ksone</i>	General Kolmogorov-Smirnov one-sided test.
<i>kstwobign</i>	Kolmogorov-Smirnov two-sided test for large N.
<i>laplace</i>	A Laplace continuous random variable.
<i>levy</i>	A Levy continuous random variable.
<i>levy_l</i>	A left-skewed Levy continuous random variable.
<i>levy_stable</i>	A Levy-stable continuous random variable.
<i>logistic</i>	A logistic (or Sech-squared) continuous random variable.
<i>loggamma</i>	A log gamma continuous random variable.
<i>loglaplace</i>	A log-Laplace continuous random variable.
<i>lognorm</i>	A lognormal continuous random variable.
<i>lomax</i>	A Lomax (Pareto of the second kind) continuous random variable.
<i>maxwell</i>	A Maxwell continuous random variable.
<i>mielke</i>	A Mielke Beta-Kappa continuous random variable.
<i>moyal</i>	A Moyal continuous random variable.
<i>nakagami</i>	A Nakagami continuous random variable.
<i>ncx2</i>	A non-central chi-squared continuous random variable.
<i>ncf</i>	A non-central F distribution continuous random variable.
<i>nct</i>	A non-central Student's t continuous random variable.
<i>norm</i>	A normal continuous random variable.
<i>norminvgauss</i>	A Normal Inverse Gaussian continuous random variable.
<i>pareto</i>	A Pareto continuous random variable.
<i>pearson3</i>	A pearson type III continuous random variable.
<i>powerlaw</i>	A power-function continuous random variable.
<i>powerlognorm</i>	A power log-normal continuous random variable.
<i>powernorm</i>	A power normal continuous random variable.
<i>rdist</i>	An R-distributed continuous random variable.
<i>reciprocal</i>	A reciprocal continuous random variable.
<i>rayleigh</i>	A Rayleigh continuous random variable.
<i>rice</i>	A Rice continuous random variable.
<i>recipinvgauss</i>	A reciprocal inverse Gaussian continuous random variable.
<i>semicircular</i>	A semicircular continuous random variable.
<i>skewnorm</i>	A skew-normal random variable.
<i>t</i>	A Student's t continuous random variable.
<i>trapz</i>	A trapezoidal continuous random variable.
<i>triang</i>	A triangular continuous random variable.
<i>truncexpon</i>	A truncated exponential continuous random variable.
<i>truncnorm</i>	A truncated normal continuous random variable.
<i>tukeylambda</i>	A Tukey-Lambda continuous random variable.

Continued on next page

Table 252 – continued from previous page

<i>uniform</i>	A uniform continuous random variable.
<i>vonmises</i>	A Von Mises continuous random variable.
<i>vonmises_line</i>	A Von Mises continuous random variable.
<i>wald</i>	A Wald continuous random variable.
<i>weibull_min</i>	Weibull minimum continuous random variable.
<i>weibull_max</i>	Weibull maximum continuous random variable.
<i>wrapcauchy</i>	A wrapped Cauchy continuous random variable.

## scipy.stats.alpha

`scipy.stats.alpha` = <`scipy.stats._continuous_distns.alpha_gen` object>

An alpha continuous random variable.

As an instance of the `rv_continuous` class, `alpha` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `alpha` is:

$$f(x, a) = \frac{1}{x^2 \Phi(a) \sqrt{2\pi}} * \exp\left(-\frac{1}{2}(a - 1/x)^2\right)$$

where  $\Phi$  is the normal CDF,  $x > 0$ , and  $a > 0$ .

`alpha` takes `a` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `alpha.pdf(x, a, loc, scale)` is identically equivalent to `alpha.pdf(y, a) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import alpha
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 3.57
>>> mean, var, skew, kurt = alpha.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(alpha.ppf(0.01, a),
... alpha.ppf(0.99, a), 100)
>>> ax.plot(x, alpha.pdf(x, a),
... 'r-', lw=5, alpha=0.6, label='alpha pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = alpha(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = alpha.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], alpha.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = alpha.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats anglit

`scipy.stats.anglit = <scipy.stats._continuous_distns.anglit_gen object>`

An *anglit* continuous random variable.

As an instance of the *rv\_continuous* class, *anglit* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *anglit* is:

$$f(x) = \sin(2x + \pi/2) = \cos(2x)$$

for  $-\pi/4 \leq x \leq \pi/4$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `anglit.pdf(x, loc, scale)` is identically equivalent to `anglit.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import anglit
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = anglit.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(anglit.ppf(0.01),
... anglit.ppf(0.99), 100)
>>> ax.plot(x, anglit.pdf(x),
... 'r-', lw=5, alpha=0.6, label='anglit pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = anglit()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = anglit.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], anglit.cdf(vals))
True
```

Generate random numbers:

```
>>> r = anglit.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.arcsine

`scipy.stats.arcsine` = `<scipy.stats._continuous_distns.arcsine_gen object>`  
 An arcsine continuous random variable.

As an instance of the `rv_continuous` class, `arcsine` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `arcsine` is:

$$f(x) = \frac{1}{\pi\sqrt{x(1-x)}}$$

for  $0 < x < 1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `arcsine.pdf(x, loc, scale)` is identically equivalent to `arcsine.pdf(y) / scale` with `y = (x - loc) / scale`.

## Examples

```
>>> from scipy.stats import arcsine
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = arcsine.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(arcsine.ppf(0.01),
... arcsine.ppf(0.99), 100)
>>> ax.plot(x, arcsine.pdf(x),
... 'r-', lw=5, alpha=0.6, label='arcsine pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = arcsine()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = arcsine.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], arcsine.cdf(vals))
True
```

Generate random numbers:

```
>>> r = arcsine.rvs(size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.argus

`scipy.stats.argus` = <`scipy.stats._continuous_distns.argus_gen` object>

Argus distribution

As an instance of the `rv_continuous` class, `argus` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `argus` is:

$$f(x, \chi) = \frac{\chi^3}{\sqrt{2\pi}\Psi(\chi)} x \sqrt{1-x^2} \exp(-\chi^2(1-x^2)/2)$$

for  $0 < x < 1$ , where

$$\Psi(\chi) = \Phi(\chi) - \chi\phi(\chi) - 1/2$$

with  $\Phi$  and  $\phi$  being the CDF and PDF of a standard normal distribution, respectively.

`argus` takes  $\chi$  as shape a parameter.

### References

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `argus.pdf(x, chi, loc, scale)` is identically equivalent to `argus.pdf(y, chi) / scale` with `y = (x - loc) / scale`.

New in version 0.19.0.

[1]

### Examples

```
>>> from scipy.stats import argus
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> chi = 1
>>> mean, var, skew, kurt = argus.stats(chi, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(argus.ppf(0.01, chi),
... argus.ppf(0.99, chi), 100)
>>> ax.plot(x, argus.pdf(x, chi),
... 'r-', lw=5, alpha=0.6, label='argus pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = argus(chi)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = argus.ppf([0.001, 0.5, 0.999], chi)
>>> np.allclose([0.001, 0.5, 0.999], argus.cdf(vals, chi))
True
```

Generate random numbers:

```
>>> r = argus.rvs(chi, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(chi, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, chi, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, chi, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, chi, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, chi, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, chi, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, chi, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, chi, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, chi, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, chi, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(chi, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(chi, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, chi, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(chi,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(chi, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(chi, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(chi, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(chi, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, chi, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.beta

`scipy.stats.beta = <scipy.stats._continuous_distns.beta_gen object>`

A beta continuous random variable.

As an instance of the *rv\_continuous* class, *beta* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *beta* is:

$$f(x, a, b) = \frac{\Gamma(a + b)x^{a-1}(1 - x)^{b-1}}{\Gamma(a)\Gamma(b)}$$

for  $0 \leq x \leq 1$ ,  $a > 0$ ,  $b > 0$ , where  $\Gamma$  is the gamma function (*scipy.special.gamma*).

*beta* takes *a* and *b* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `beta.pdf(x, a, b, loc, scale)` is identically equivalent to `beta.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import beta
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 2.31, 0.627
>>> mean, var, skew, kurt = beta.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(beta.ppf(0.01, a, b),
... beta.ppf(0.99, a, b), 100)
>>> ax.plot(x, beta.pdf(x, a, b),
... 'r-', lw=5, alpha=0.6, label='beta pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = beta(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = beta.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], beta.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = beta.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, b, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.betaprime

`scipy.stats.betaprime` = <scipy.stats.\_continuous\_distns.betaprime\_gen object>  
 A beta prime continuous random variable.

As an instance of the `rv_continuous` class, `betaprime` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `betaprime` is:

$$f(x, a, b) = \frac{x^{a-1}(1+x)^{-a-b}}{\beta(a, b)}$$

for  $x \geq 0$ ,  $a > 0$ ,  $b > 0$ , where  $\beta(a, b)$  is the beta function (see `scipy.special.beta`).

`betaprime` takes `a` and `b` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `betaprime.pdf(x, a, b, loc, scale)` is identically equivalent to `betaprime.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import betaprime
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 5, 6
>>> mean, var, skew, kurt = betaprime.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(betaprime.ppf(0.01, a, b),
... betaprime.ppf(0.99, a, b), 100)
>>> ax.plot(x, betaprime.pdf(x, a, b),
... 'r-', lw=5, alpha=0.6, label='betaprime pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = betaprime(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = betaprime.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], betaprime.cdf(vals, a, b))
True
```

Generate random numbers:

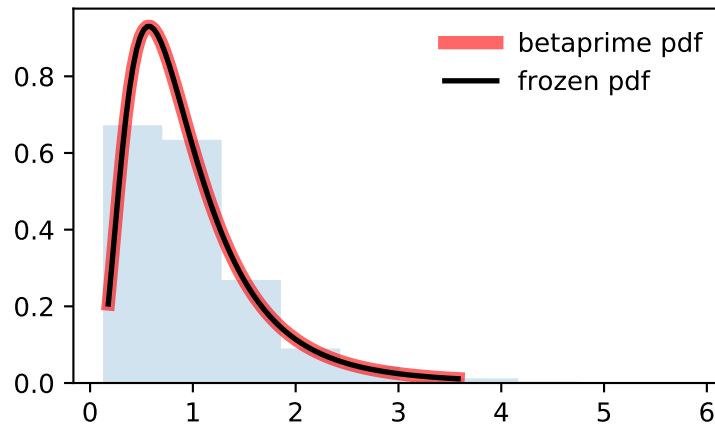

```
>>> r = betaprime.rvs(a, b, size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

## Methods

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, b, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, loc=0, scale=1)</code>	Endpoints of the range that contains <i>alpha</i> percent of the distribution

## scipy.stats.bradford

`scipy.stats.bradford` = <scipy.stats.\_continuous\_distns.bradford\_gen object>  
A Bradford continuous random variable.

As an instance of the `rv_continuous` class, `bradford` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `bradford` is:

$$f(x, c) = \frac{c}{\log(1+c)(1+cx)}$$

for  $0 \leq x \leq 1$  and  $c > 0$ .

`bradford` takes `c` as a shape parameter for `c`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `bradford.pdf(x, c, loc, scale)` is identically equivalent to `bradford.pdf(y, c) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import bradford
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.299
>>> mean, var, skew, kurt = bradford.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(bradford.ppf(0.01, c),
... bradford.ppf(0.99, c), 100)
>>> ax.plot(x, bradford.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='bradford pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = bradford(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

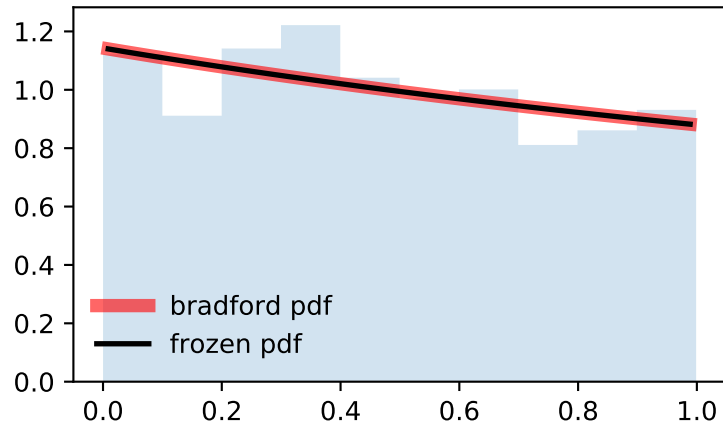

```
>>> vals = bradford.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], bradford.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = bradford.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').

<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.burr

`scipy.stats.burr = <scipy.stats._continuous_distns.burr_gen object>`

A Burr (Type III) continuous random variable.

As an instance of the `rv_continuous` class, `burr` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

### `fisk`

a special case of either `burr` or `burr12` with  $d=1$

### `burr12`

Burr Type XII distribution

## Notes

The probability density function for `burr` is:

$$f(x, c, d) = cdx^{-c-1}(1+x^{-c})^{-d-1}$$

for  $x \geq 0$  and  $c, d > 0$ .

`burr` takes  $c$  and  $d$  as shape parameters.

This is the PDF corresponding to the third CDF given in Burr’s list; specifically, it is equation (11) in Burr’s paper [1].

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `burr.pdf(x, c, d, loc, scale)` is identically equivalent to `burr.pdf(y, c, d) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## References

[1]

## Examples

```
>>> from scipy.stats import burr
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c, d = 10.5, 4.3
>>> mean, var, skew, kurt = burr.stats(c, d, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(burr.ppf(0.01, c, d),
... burr.ppf(0.99, c, d), 100)
>>> ax.plot(x, burr.pdf(x, c, d),
... 'r-', lw=5, alpha=0.6, label='burr pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = burr(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = burr.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], burr.cdf(vals, c, d))
True
```

Generate random numbers:

```
>>> r = burr.rvs(c, d, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>interval(alpha, c, d, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## `scipy.stats.burr12`

`scipy.stats.burr12` = <`scipy.stats._continuous_distns.burr12_gen` object>  
 A Burr (Type XII) continuous random variable.

As an instance of the `rv_continuous` class, `burr12` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

**fisk**

a special case of either `burr` or `burr12` with `d=1`

**burr**

Burr Type III distribution

## Notes

The probability density function for `burr` is:

$$f(x, c, d) = cdx^{c-1}(1+x^c)^{-d-1}$$

for  $x \geq 0$  and  $c, d > 0$ .

`burr12` takes `c` and `d` as shape parameters for `c` and `d`.

This is the PDF corresponding to the twelfth CDF given in Burr's list; specifically, it is equation (20) in Burr's paper [1].

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `burr12.pdf(x, c, d, loc, scale)` is identically equivalent to `burr12.pdf(y, c, d) / scale` with `y = (x - loc) / scale`.

The Burr type 12 distribution is also sometimes referred to as the Singh-Maddala distribution from NIST [2].

## References

[1], [2]

## Examples

```
>>> from scipy.stats import burr12
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c, d = 10, 4
>>> mean, var, skew, kurt = burr12.stats(c, d, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(burr12.ppf(0.01, c, d),
... burr12.ppf(0.99, c, d), 100)
>>> ax.plot(x, burr12.pdf(x, c, d),
... 'r-', lw=5, alpha=0.6, label='burr12 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = burr12(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = burr12.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], burr12.cdf(vals, c, d))
True
```

Generate random numbers:

```
>>> r = burr12.rvs(c, d, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.cauchy

`scipy.stats.cauchy = <scipy.stats._continuous_distns.cauchy_gen object>`

A Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `cauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `cauchy` is

$$f(x) = \frac{1}{\pi(1+x^2)}$$

for a real number  $x$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `cauchy.pdf(x, loc, scale)` is identically equivalent to `cauchy.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import cauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = cauchy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(cauchy.ppf(0.01),
... cauchy.ppf(0.99), 100)
>>> ax.plot(x, cauchy.pdf(x),
... 'r-', lw=5, alpha=0.6, label='cauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = cauchy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = cauchy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], cauchy.cdf(vals))
True
```

Generate random numbers:

```
>>> r = cauchy.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.chi

`scipy.stats.chi` = <`scipy.stats._continuous_distns.chi_gen` object>  
 A chi continuous random variable.

As an instance of the `rv_continuous` class, `chi` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `chi` is:

$$f(x, k) = \frac{1}{2^{k/2-1} \Gamma(k/2)} x^{k-1} \exp(-x^2/2)$$

for  $x \geq 0$  and  $k > 0$  (degrees of freedom, denoted `df` in the implementation).  $\Gamma$  is the gamma function (`scipy.special.gamma`).

Special cases of `chi` are:

- `chi(1, loc, scale)` is equivalent to `halfnorm`
- `chi(2, 0, scale)` is equivalent to `rayleigh`
- `chi(3, 0, scale)` is equivalent to `maxwell`

`chi` takes `df` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `chi.pdf(x, df, loc, scale)` is identically equivalent to `chi.pdf(y, df) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import chi
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> df = 78
>>> mean, var, skew, kurt = chi.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(chi.ppf(0.01, df),
... chi.ppf(0.99, df), 100)
>>> ax.plot(x, chi.pdf(x, df),
... 'r-', lw=5, alpha=0.6, label='chi pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = chi(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = chi.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], chi.cdf(vals, df))
True
```

Generate random numbers:

```
>>> r = chi.rvs(df, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(df, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, df, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, df, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, df, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, df, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, df, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, df, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, df, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, df, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, df, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(df, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(df, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, df, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(df,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(df, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(df, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(df, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(df, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, df, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.chi2

`scipy.stats.chi2 = <scipy.stats._continuous_distns.chi2_gen object>`

A chi-squared continuous random variable.

As an instance of the `rv_continuous` class, `chi2` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `chi2` is:

$$f(x, k) = \frac{1}{2^{k/2} \Gamma(k/2)} x^{k/2-1} \exp(-x/2)$$

for  $x > 0$  and  $k > 0$  (degrees of freedom, denoted `df` in the implementation).

`chi2` takes `df` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `chi2.pdf(x, df, loc, scale)` is identically equivalent to `chi2.pdf(y, df) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import chi2
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> df = 55
>>> mean, var, skew, kurt = chi2.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(chi2.ppf(0.01, df),
... chi2.ppf(0.99, df), 100)
>>> ax.plot(x, chi2.pdf(x, df),
... 'r-', lw=5, alpha=0.6, label='chi2 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = chi2(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = chi2.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], chi2.cdf(vals, df))
True
```

Generate random numbers:

```
>>> r = chi2.rvs(df, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(df, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, df, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, df, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, df, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, df, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, df, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, df, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, df, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, df, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, df, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(df, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(df, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, df, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(df,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(df, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(df, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(df, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(df, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, df, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.cosine

`scipy.stats.cosine = <scipy.stats._continuous_distns.cosine_gen object>`  
 A cosine continuous random variable.

As an instance of the `rv_continuous` class, `cosine` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The cosine distribution is an approximation to the normal distribution. The probability density function for `cosine` is:

$$f(x) = \frac{1}{2\pi}(1 + \cos(x))$$

for  $-\pi \leq x \leq \pi$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `cosine.pdf(x, loc, scale)` is identically equivalent to `cosine.pdf(y) / scale` with `y = (x - loc) / scale`.

## Examples

```
>>> from scipy.stats import cosine
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = cosine.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(cosine.ppf(0.01),
... cosine.ppf(0.99), 100)
>>> ax.plot(x, cosine.pdf(x),
... 'r-', lw=5, alpha=0.6, label='cosine pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = cosine()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = cosine.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], cosine.cdf(vals))
True
```

Generate random numbers:

```
>>> r = cosine.rvs(size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>

<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.crystalball

`scipy.stats.crystalball` = <`scipy.stats._continuous_distns.crystalball_gen` object>  
Crystalball distribution

As an instance of the `rv_continuous` class, `crystalball` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `crystalball` is:

$$f(x, \beta, m) = \begin{cases} N \exp(-x^2/2), & \text{for } x > -\beta \\ NA(B - x)^{-m} & \text{for } x \leq -\beta \end{cases}$$

where  $A = (m/|\beta|)^n \exp(-\beta^2/2)$ ,  $B = m/|\beta| - |\beta|$  and  $N$  is a normalisation constant.

`crystalball` takes  $\beta > 0$  and  $m > 1$  as shape parameters.  $\beta$  defines the point where the pdf changes from a power-law to a Gaussian distribution.  $m$  is the power of the power-law tail.

### References

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `crystalball.pdf(x, beta, m, loc, scale)` is identically equivalent to `crystalball.pdf(y, beta, m) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

New in version 0.19.0.

[1]

### Examples

```
>>> from scipy.stats import crystalball
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> beta, m = 2, 3
>>> mean, var, skew, kurt = crystalball.stats(beta, m, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(crystalball.ppf(0.01, beta, m),
... crystalball.ppf(0.99, beta, m), 100)
>>> ax.plot(x, crystalball.pdf(x, beta, m),
... 'r-', lw=5, alpha=0.6, label='crystalball pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = crystalball(beta, m)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

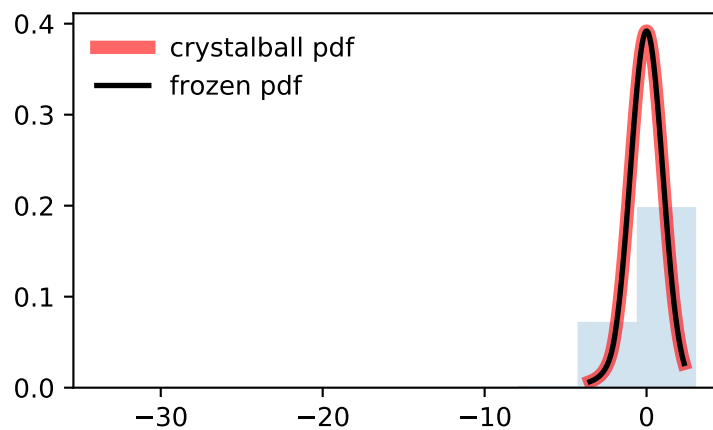

```
>>> vals = crystalball.ppf([0.001, 0.5, 0.999], beta, m)
>>> np.allclose([0.001, 0.5, 0.999], crystalball.cdf(vals, beta, m))
True
```

Generate random numbers:

```
>>> r = crystalball.rvs(beta, m, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(beta, m, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, beta, m, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, beta, m, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, beta, m, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, beta, m, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, beta, m, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, beta, m, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, beta, m, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, beta, m, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).

<code>stats(beta, m, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(beta, m, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, beta, m, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(beta, m), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(beta, m, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(beta, m, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(beta, m, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(beta, m, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, beta, m, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.dgamma

`scipy.stats.dgamma = <scipy.stats._continuous_distns.dgamma_gen object>`

A double gamma continuous random variable.

As an instance of the `rv_continuous` class, `dgamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `dgamma` is:

$$f(x, a) = \frac{1}{2\Gamma(a)} |x|^{a-1} \exp(-|x|)$$

for a real number  $x$  and  $a > 0$ .  $\Gamma$  is the gamma function (`scipy.special.gamma`).

`dgamma` takes  $a$  as a shape parameter for  $a$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `dgamma.pdf(x, a, loc, scale)` is identically equivalent to `dgamma.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import dgamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 1.1
>>> mean, var, skew, kurt = dgamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(dgamma.ppf(0.01, a),
... dgamma.ppf(0.99, a), 100)
>>> ax.plot(x, dgamma.pdf(x, a),
... 'r-', lw=5, alpha=0.6, label='dgamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = dgamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = dgamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], dgamma.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = dgamma.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.dweibull

`scipy.stats.dweibull = <scipy.stats._continuous_distns.dweibull_gen object>`  
 A double Weibull continuous random variable.

As an instance of the `rv_continuous` class, `dweibull` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `dweibull` is given by

$$f(x, c) = c/2|x|^{c-1} \exp(-|x|^c)$$

for a real number  $x$  and  $c > 0$ .

`dweibull` takes  $c$  as a shape parameter for  $c$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `dweibull.pdf(x, c, loc, scale)` is identically equivalent to `dweibull.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import dweibull
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 2.07
>>> mean, var, skew, kurt = dweibull.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(dweibull.ppf(0.01, c),
... dweibull.ppf(0.99, c), 100)
>>> ax.plot(x, dweibull.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='dweibull pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = dweibull(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = dweibull.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], dweibull.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = dweibull.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains <i>alpha</i> percent of the distribution

## scipy.stats.erlang

`scipy.stats.erlang` = <`scipy.stats._continuous_distns.erlang_gen` object>

An Erlang continuous random variable.

As an instance of the `rv_continuous` class, `erlang` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[\*gamma\*](#)

### Notes

The Erlang distribution is a special case of the Gamma distribution, with the shape parameter  $a$  an integer. Note that this restriction is not enforced by `erlang`. It will, however, generate a warning the first time a non-integer value is used for the shape parameter.

Refer to [\*gamma\*](#) for examples.

### Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, a, loc=0, scale=1)</code>	Non-central moment of order $n$
<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.expon

`scipy.stats.expon` = <`scipy.stats._continuous_distns.expon_gen` object>

An exponential continuous random variable.

As an instance of the `rv_continuous` class, `expon` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `expon` is:

$$f(x) = \exp(-x)$$

for  $x \geq 0$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `expon.pdf(x, loc, scale)` is identically equivalent to `expon.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

A common parameterization for `expon` is in terms of the rate parameter `lambda`, such that `pdf = lambda * exp(-lambda * x)`. This parameterization corresponds to using `scale = 1 / lambda`.

## Examples

```
>>> from scipy.stats import expon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = expon.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(expon.ppf(0.01),
... expon.ppf(0.99), 100)
>>> ax.plot(x, expon.pdf(x),
... 'r-', lw=5, alpha=0.6, label='expon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = expon()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = expon.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], expon.cdf(vals))
True
```

Generate random numbers:

```
>>> r = expon.rvs(size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.exponnorm

`scipy.stats.exponnorm` = <`scipy.stats._continuous_distns.exponnorm_gen` object>  
 An exponentially modified Normal continuous random variable.

As an instance of the `rv_continuous` class, `exponnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `exponnorm` is:

$$f(x, K) = \frac{1}{2K} \exp\left(\frac{1}{2K^2} - x/K\right) \operatorname{erfc}\left(-\frac{x - 1/K}{\sqrt{2}}\right)$$

where  $x$  is a real number and  $K > 0$ .

It can be thought of as the sum of a standard normal random variable and an independent exponentially distributed random variable with rate  $1/K$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `exponnorm.pdf(x, K, loc, scale)` is identically equivalent to `exponnorm.pdf(y, K) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

An alternative parameterization of this distribution (for example, in [Wikipedia](#)) involves three parameters,  $\mu$ ,  $\lambda$  and  $\sigma$ . In the present parameterization this corresponds to having `loc` and `scale` equal to  $\mu$  and  $\sigma$ , respectively, and shape parameter  $K = 1/(\sigma\lambda)$ .

New in version 0.16.0.

### Examples

```
>>> from scipy.stats import exponnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> K = 1.5
>>> mean, var, skew, kurt = exponnorm.stats(K, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(exponnorm.ppf(0.01, K),
... exponnorm.ppf(0.99, K), 100)
>>> ax.plot(x, exponnorm.pdf(x, K),
... 'r-', lw=5, alpha=0.6, label='exponnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = exponnorm(K)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = exponnorm.ppf([0.001, 0.5, 0.999], K)
>>> np.allclose([0.001, 0.5, 0.999], exponnorm.cdf(vals, K))
True
```

Generate random numbers:

```
>>> r = exponnorm.rvs(K, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(K, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, K, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, K, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, K, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, K, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, K, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, K, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, K, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, K, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, K, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(K, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(K, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, K, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(K,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(K, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(K, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(K, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(K, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, K, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.exponweib

`scipy.stats.exponweib` = <scipy.stats.\_continuous\_distns.exponweib\_gen object>  
An exponentiated Weibull continuous random variable.

As an instance of the *rv\_continuous* class, *exponweib* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *exponweib* is:

$$f(x, a, c) = ac(1 - \exp(-x^c))^{a-1} \exp(-x^c)x^{c-1}$$

for  $x \geq 0, a > 0, c > 0$ .

*exponweib* takes *a* and *c* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `exponweib.pdf(x, a, c, loc, scale)` is identically equivalent to `exponweib.pdf(y, a, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import exponweib
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, c = 2.89, 1.95
>>> mean, var, skew, kurt = exponweib.stats(a, c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(exponweib.ppf(0.01, a, c),
... exponweib.ppf(0.99, a, c), 100)
>>> ax.plot(x, exponweib.pdf(x, a, c),
... 'r-', lw=5, alpha=0.6, label='exponweib pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = exponweib(a, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = exponweib.ppf([0.001, 0.5, 0.999], a, c)
>>> np.allclose([0.001, 0.5, 0.999], exponweib.cdf(vals, a, c))
True
```

Generate random numbers:

```
>>> r = exponweib.rvs(a, c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a, c), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, c, loc=0, scale=1)</code>	Endpoints of the range that contains <i>alpha</i> percent of the distribution

## scipy.stats.exponpow

`scipy.stats.exponpow = <scipy.stats._continuous_distns.exponpow_gen object>`  
 An exponential power continuous random variable.

As an instance of the `rv_continuous` class, `exponpow` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `exponpow` is:

$$f(x, b) = bx^{b-1} \exp(1 + x^b - \exp(x^b))$$

for  $x \geq 0, b > 0$ . Note that this is a different distribution from the exponential power distribution that is also known under the names “generalized normal” or “generalized Gaussian”.

`exponpow` takes `b` as a shape parameter for  $b$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `exponpow.pdf(x, b, loc, scale)` is identically equivalent to `exponpow.pdf(y, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## References

<http://www.math.wm.edu/~leemis/chart/UDR/PDFs/Exponentialpower.pdf>

## Examples

```
>>> from scipy.stats import exponpow
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> b = 2.7
>>> mean, var, skew, kurt = exponpow.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(exponpow.ppf(0.01, b),
... exponpow.ppf(0.99, b), 100)
>>> ax.plot(x, exponpow.pdf(x, b),
... 'r-', lw=5, alpha=0.6, label='exponpow pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = exponpow(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = exponpow.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], exponpow.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = exponpow.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>mean(b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.f

`scipy.stats.f = <scipy.stats._continuous_distns.f_gen object>`

An F continuous random variable.

As an instance of the `rv_continuous` class, *f* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *f* is:

$$f(x, df_1, df_2) = \frac{df_2^{df_2/2} df_1^{df_1/2} x^{df_1/2-1}}{(df_2 + df_1 x)^{(df_1+df_2)/2} B(df_1/2, df_2/2)}$$

for  $x > 0$ .

*f* takes *dfn* and *dfd* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `f.pdf(x, dfn, dfd, loc, scale)` is identically equivalent to `f.pdf(y, dfn, dfd) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import f
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> dfn, dfd = 29, 18
>>> mean, var, skew, kurt = f.stats(dfn, dfd, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(f.ppf(0.01, dfn, dfd),
... f.ppf(0.99, dfn, dfd), 100)
>>> ax.plot(x, f.pdf(x, dfn, dfd),
... 'r-', lw=5, alpha=0.6, label='f pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = f(dfn, dfd)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = f.ppf([0.001, 0.5, 0.999], dfn, dfd)
>>> np.allclose([0.001, 0.5, 0.999], f.cdf(vals, dfn, dfd))
True
```

Generate random numbers:

```
>>> r = f.rvs(dfn, dfd, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(dfn, dfd, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, dfn, dfd, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, dfn, dfd, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, dfn, dfd, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, dfn, dfd, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, dfn, dfd, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, dfn, dfd, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, dfn, dfd, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, dfn, dfd, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, dfn, dfd, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(dfn, dfd, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(dfn, dfd, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, dfn, dfd, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(dfn, dfd), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(dfn, dfd, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(dfn, dfd, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(dfn, dfd, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(dfn, dfd, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, dfn, dfd, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.fatiguelife

`scipy.stats.fatiguelife` = <scipy.stats.\_continuous\_distns.fatiguelife\_gen object>  
 A fatigue-life (Birnbbaum-Saunders) continuous random variable.

As an instance of the `rv_continuous` class, `fatiguelife` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `fatiguelife` is:

$$f(x, c) = \frac{x + 1}{2c\sqrt{2\pi x^3}} \exp\left(-\frac{(x - 1)^2}{2xc^2}\right)$$

for  $x \geq 0$  and  $c > 0$ .

`fatiguelife` takes `c` as a shape parameter for  $c$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `fatiguelife.pdf(x, c, loc, scale)` is identically equivalent to `fatiguelife.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## References

[1]

## Examples

```
>>> from scipy.stats import fatiguelife
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 29
>>> mean, var, skew, kurt = fatiguelife.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(fatiguelife.ppf(0.01, c),
... fatiguelife.ppf(0.99, c), 100)
>>> ax.plot(x, fatiguelife.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='fatiguelife pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = fatiguelife(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = fatiguelife.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], fatiguelife.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = fatiguelife.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.fisk

`scipy.stats.fisk = <scipy.stats._continuous_distns.fisk_gen object>`

A Fisk continuous random variable.

The Fisk distribution is also known as the log-logistic distribution.

As an instance of the *rv\_continuous* class, *fisk* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

*burr*

## Notes

The probability density function for *fisk* is:

$$f(x, c) = cx^{-c-1}(1 + x^{-c})^{-2}$$

for  $x \geq 0$  and  $c > 0$ .

*fisk* takes *c* as a shape parameter for *c*.

*fisk* is a special case of *burr* or *burr12* with *d*=1.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `fisk.pdf(x, c, loc, scale)` is identically equivalent to `fisk.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import fisk
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 3.09
>>> mean, var, skew, kurt = fisk.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(fisk.ppf(0.01, c),
... fisk.ppf(0.99, c), 100)
>>> ax.plot(x, fisk.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='fisk pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = fisk(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = fisk.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], fisk.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = fisk.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>

<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## `scipy.stats.foldcauchy`

`scipy.stats.foldcauchy = <scipy.stats._continuous_distns.foldcauchy_gen object>`  
 A folded Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `foldcauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `foldcauchy` is:

$$f(x, c) = \frac{1}{\pi(1 + (x - c)^2)} + \frac{1}{\pi(1 + (x + c)^2)}$$

for  $x \geq 0$ .

`foldcauchy` takes `c` as a shape parameter for  $c$ .

## Examples

```
>>> from scipy.stats import foldcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 4.72
>>> mean, var, skew, kurt = foldcauchy.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(foldcauchy.ppf(0.01, c),
... foldcauchy.ppf(0.99, c), 100)
>>> ax.plot(x, foldcauchy.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='foldcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = foldcauchy(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = foldcauchy.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], foldcauchy.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = foldcauchy.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.foldnorm

`scipy.stats.foldnorm = <scipy.stats._continuous_distns.foldnorm_gen object>`  
 A folded normal continuous random variable.

As an instance of the `rv_continuous` class, `foldnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `foldnorm` is:

$$f(x, c) = \sqrt{2/\pi} \cosh(cx) \exp\left(-\frac{x^2 + c^2}{2}\right)$$

for  $c \geq 0$ .

`foldnorm` takes `c` as a shape parameter for `c`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `foldnorm.pdf(x, c, loc, scale)` is identically equivalent to `foldnorm.pdf(y, c) / scale` with `y = (x - loc) / scale`.

## Examples

```
>>> from scipy.stats import foldnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 1.95
>>> mean, var, skew, kurt = foldnorm.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(foldnorm.ppf(0.01, c),
... foldnorm.ppf(0.99, c), 100)
>>> ax.plot(x, foldnorm.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='foldnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = foldnorm(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = foldnorm.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], foldnorm.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = foldnorm.rvs(c, size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains <i>alpha</i> percent of the distribution

## scipy.stats.frechet\_r

`scipy.stats.frechet_r` = <scipy.stats.\_continuous\_distns.frechet\_r\_gen object>  
A Frechet right (or Weibull minimum) continuous random variable.

As an instance of the *rv\_continuous* class, *frechet\_r* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

### `weibull_min`

The same distribution as *frechet\_r*.

## Notes

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `frechet_r.pdf(x, c, loc, scale)` is identically equivalent to `frechet_r.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import frechet_r
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 1.89
>>> mean, var, skew, kurt = frechet_r.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(frechet_r.ppf(0.01, c),
... frechet_r.ppf(0.99, c), 100)
>>> ax.plot(x, frechet_r.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='frechet_r pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = frechet_r(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = frechet_r.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], frechet_r.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = frechet_r.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.frechet\_l

`scipy.stats.frechet_l = <scipy.stats._continuous_distns.frechet_l_gen object>`

A Frechet left (or Weibull maximum) continuous random variable.

As an instance of the *rv\_continuous* class, *frechet\_l* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

### `weibull_max`

The same distribution as *frechet\_l*.

## Notes

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `frechet_l.pdf(x, c, loc, scale)` is identically equivalent to `frechet_l.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import frechet_1
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 3.63
>>> mean, var, skew, kurt = frechet_1.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(frechet_1.ppf(0.01, c),
... frechet_1.ppf(0.99, c), 100)
>>> ax.plot(x, frechet_1.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='frechet_1 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = frechet_1(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = frechet_1.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], frechet_1.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = frechet_1.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.genlogistic

`scipy.stats.genlogistic` = <scipy.stats.\_continuous\_distns.genlogistic\_gen object>  
 A generalized logistic continuous random variable.

As an instance of the `rv_continuous` class, `genlogistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `genlogistic` is:

$$f(x, c) = c \frac{\exp(-x)}{(1 + \exp(-x))^{c+1}}$$

for  $x \geq 0, c > 0$ .

`genlogistic` takes `c` as a shape parameter for  $c$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genlogistic.pdf(x, c, loc, scale)` is identically equivalent to `genlogistic.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import genlogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.412
>>> mean, var, skew, kurt = genlogistic.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genlogistic.ppf(0.01, c),
... genlogistic.ppf(0.99, c), 100)
>>> ax.plot(x, genlogistic.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='genlogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genlogistic(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genlogistic.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genlogistic.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genlogistic.rvs(c, size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains <i>alpha</i> percent of the distribution

## scipy.stats.gennorm

`scipy.stats.gennorm` = <`scipy.stats._continuous_distns.gennorm_gen` object>

A generalized normal continuous random variable.

As an instance of the `rv_continuous` class, `gennorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

### `laplace`

Laplace distribution

### `norm`

normal distribution

## Notes

The probability density function for `gennorm` is [1]:

$$f(x, \beta) = \frac{\beta}{2\Gamma(1/\beta)} \exp(-|x|^\beta)$$

$\Gamma$  is the gamma function (`scipy.special.gamma`).

`gennorm` takes `beta` as a shape parameter for  $\beta$ . For  $\beta = 1$ , it is identical to a Laplace distribution. For  $\beta = 2$ , it is identical to a normal distribution (with `scale=1/sqrt(2)`).

## References

## Examples

```
>>> from scipy.stats import gennorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> beta = 1.3
>>> mean, var, skew, kurt = gennorm.stats(beta, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gennorm.ppf(0.01, beta),
... gennorm.ppf(0.99, beta), 100)
>>> ax.plot(x, gennorm.pdf(x, beta),
... 'r-', lw=5, alpha=0.6, label='gennorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gennorm(beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gennorm.ppf([0.001, 0.5, 0.999], beta)
>>> np.allclose([0.001, 0.5, 0.999], gennorm.cdf(vals, beta))
True
```

Generate random numbers:

```
>>> r = gennorm.rvs(beta, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(beta, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, beta, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, beta, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, beta, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, beta, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, beta, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).

<code>median(beta, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(beta, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(beta, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(beta, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, beta, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.genpareto

`scipy.stats.genpareto = <scipy.stats._continuous_distns.genpareto_gen object>`

A generalized Pareto continuous random variable.

As an instance of the *rv\_continuous* class, *genpareto* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *genpareto* is:

$$f(x, c) = (1 + cx)^{-1-1/c}$$

defined for  $x \geq 0$  if  $c \geq 0$ , and for  $0 \leq x \leq -1/c$  if  $c < 0$ .

*genpareto* takes *c* as a shape parameter for *c*.

For  $c = 0$ , *genpareto* reduces to the exponential distribution, *expon*:

$$f(x, 0) = \exp(-x)$$

For  $c = -1$ , *genpareto* is uniform on  $[0, 1]$ :

$$f(x, -1) = 1$$

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genpareto.pdf(x, c, loc, scale)` is identically equivalent to `genpareto.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import genpareto
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.1
>>> mean, var, skew, kurt = genpareto.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genpareto.ppf(0.01, c),
... genpareto.ppf(0.99, c), 100)
>>> ax.plot(x, genpareto.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='genpareto pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genpareto(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genpareto.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genpareto.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genpareto.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.genexpon

`scipy.stats.genexpon = <scipy.stats._continuous_distns.genexpon_gen object>`  
 A generalized exponential continuous random variable.

As an instance of the `rv_continuous` class, `genexpon` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `genexpon` is:

$$f(x, a, b, c) = (a + b(1 - \exp(-cx))) \exp(-ax - bx + \frac{b}{c}(1 - \exp(-cx)))$$

for  $x \geq 0, a, b, c > 0$ .

`genexpon` takes  $a, b$  and  $c$  as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genexpon.pdf(x, a, b, c, loc, scale)` is identically equivalent to `genexpon.pdf(y, a, b, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import genexpon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b, c = 9.13, 16.2, 3.28
>>> mean, var, skew, kurt = genexpon.stats(a, b, c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genexpon.ppf(0.01, a, b, c),
... genexpon.ppf(0.99, a, b, c), 100)
>>> ax.plot(x, genexpon.pdf(x, a, b, c),
... 'r-', lw=5, alpha=0.6, label='genexpon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genexpon(a, b, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genexpon.ppf([0.001, 0.5, 0.999], a, b, c)
>>> np.allclose([0.001, 0.5, 0.999], genexpon.cdf(vals, a, b, c))
True
```

Generate random numbers:

```
>>> r = genexpon.rvs(a, b, c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.genextreme

`scipy.stats.genextreme` = <`scipy.stats._continuous_distns.genextreme_gen` object>  
 A generalized extreme value continuous random variable.

As an instance of the `rv_continuous` class, `genextreme` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`gumbel_r`

## Notes

For  $c = 0$ , `genextreme` is equal to `gumbel_r`. The probability density function for `genextreme` is:

$$f(x, c) = \begin{cases} \exp(-\exp(-x)) \exp(-x) & \text{for } c = 0 \\ \exp(-(1 - cx)^{1/c})(1 - cx)^{1/c-1} & \text{for } x \leq 1/c, c > 0 \end{cases}$$

Note that several sources and software packages use the opposite convention for the sign of the shape parameter  $c$ .

`genextreme` takes  $c$  as a shape parameter for  $c$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genextreme.pdf(x, c, loc, scale)` is identically equivalent to `genextreme.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import genextreme
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = -0.1
>>> mean, var, skew, kurt = genextreme.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genextreme.ppf(0.01, c),
... genextreme.ppf(0.99, c), 100)
>>> ax.plot(x, genextreme.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='genextreme pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genextreme(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genextreme.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genextreme.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genextreme.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.

<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains $\alpha$ percent of the distribution

## scipy.stats.gausshyper

`scipy.stats.gausshyper` = `<scipy.stats._continuous_distns.gausshyper_gen object>`  
 A Gauss hypergeometric continuous random variable.

As an instance of the `rv_continuous` class, `gausshyper` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `gausshyper` is:

$$f(x, a, b, c, z) = Cx^{a-1}(1-x)^{b-1}(1+zx)^{-c}$$

for  $0 \leq x \leq 1$ ,  $a > 0$ ,  $b > 0$ , and  $C = \frac{1}{B(a,b)F[2,1](c,a;a+b;-z)}$ .  $F[2, 1]$  is the Gauss hypergeometric function `scipy.special.hyp2f1`.

`gausshyper` takes  $a$ ,  $b$ ,  $c$  and  $z$  as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gausshyper.pdf(x, a, b, c, z, loc, scale)` is identically equivalent to `gausshyper.pdf(y, a, b, c, z) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import gausshyper
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b, c, z = 13.8, 3.12, 2.51, 5.18
>>> mean, var, skew, kurt = gausshyper.stats(a, b, c, z, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gausshyper.ppf(0.01, a, b, c, z),
... gausshyper.ppf(0.99, a, b, c, z), 100)
>>> ax.plot(x, gausshyper.pdf(x, a, b, c, z),
... 'r-', lw=5, alpha=0.6, label='gausshyper pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gausshyper(a, b, c, z)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gausshyper.ppf([0.001, 0.5, 0.999], a, b, c, z)
>>> np.allclose([0.001, 0.5, 0.999], gausshyper.cdf(vals, a, b, c, z))
True
```

Generate random numbers:

```
>>> r = gausshyper.rvs(a, b, c, z, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, b, c, z, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, c, z, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, c, z, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, c, z, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, c, z, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, c, z, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, c, z, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, c, z, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, b, c, z, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, b, c, z, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, b, c, z, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, b, c, z, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, b, c, z, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a, b, c, z), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, c, z, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, c, z, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, c, z, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, c, z, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, c, z, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.gamma

`scipy.stats.gamma = <scipy.stats._continuous_distns.gamma_gen object>`

A gamma continuous random variable.

As an instance of the *rv\_continuous* class, *gamma* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

*erlang*, *expon*

## Notes

The probability density function for *gamma* is:

$$f(x, a) = \frac{x^{a-1} \exp(-x)}{\Gamma(a)}$$

for  $x \geq 0$ ,  $a > 0$ . Here  $\Gamma(a)$  refers to the gamma function.

*gamma* takes *a* as a shape parameter for *a*.

When *a* is an integer, *gamma* reduces to the Erlang distribution, and when  $a = 1$  to the exponential distribution.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gamma.pdf(x, a, loc, scale)` is identically equivalent to `gamma.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import gamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 1.99
>>> mean, var, skew, kurt = gamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gamma.ppf(0.01, a),
... gamma.ppf(0.99, a), 100)
>>> ax.plot(x, gamma.pdf(x, a),
... 'r-', lw=5, alpha=0.6, label='gamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], gamma.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = gamma.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but $\text{sf}$ is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of $\text{cdf}$ — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of $\text{sf}$ ).
<code>moment(n, a, loc=0, scale=1)</code>	Non-central moment of order $n$
<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.gengamma

`scipy.stats.gengamma = <scipy.stats._continuous_distns.gengamma_gen object>`  
 A generalized gamma continuous random variable.

As an instance of the `rv_continuous` class, `gengamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `gengamma` is:

$$f(x, a, c) = \frac{|c|x^{ca-1} \exp(-x^c)}{\Gamma(a)}$$

for  $x \geq 0$ ,  $a > 0$ , and  $c \neq 0$ .  $\Gamma$  is the gamma function (`scipy.special.gamma`).

`gengamma` takes  $a$  and  $c$  as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gengamma.pdf(x, a, c, loc, scale)` is identically equivalent to `gengamma.pdf(y, a, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import gengamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, c = 4.42, -3.12
>>> mean, var, skew, kurt = gengamma.stats(a, c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gengamma.ppf(0.01, a, c),
... gengamma.ppf(0.99, a, c), 100)
>>> ax.plot(x, gengamma.pdf(x, a, c),
... 'r-', lw=5, alpha=0.6, label='gengamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gengamma(a, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gengamma.ppf([0.001, 0.5, 0.999], a, c)
>>> np.allclose([0.001, 0.5, 0.999], gengamma.cdf(vals, a, c))
True
```

Generate random numbers:

```
>>> r = gengamma.rvs(a, c, size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

## Methods

<code>rvs(a, c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a, c), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.genhalflogistic

`scipy.stats.genhalflogistic` = <`scipy.stats._continuous_distns.genhalflogistic_gen` object>  
 A generalized half-logistic continuous random variable.

As an instance of the `rv_continuous` class, `genhalflogistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `genhalflogistic` is:

$$f(x, c) = \frac{2(1 - cx)^{1/(c-1)}}{[1 + (1 - cx)^{1/c}]^2}$$

for  $0 \leq x \leq 1/c$ , and  $c > 0$ .

`genhalflogistic` takes  $c$  as a shape parameter for  $c$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genhalflogistic.pdf(x, c, loc, scale)` is identically equivalent to `genhalflogistic.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import genhalflogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.773
>>> mean, var, skew, kurt = genhalflogistic.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genhalflogistic.ppf(0.01, c),
... genhalflogistic.ppf(0.99, c), 100)
>>> ax.plot(x, genhalflogistic.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='genhalflogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genhalflogistic(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genhalflogistic.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genhalflogistic.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genhalflogistic.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.gilbrat

`scipy.stats.gilbrat = <scipy.stats._continuous_distns.gilbrat_gen object>`

A Gilbrat continuous random variable.

As an instance of the `rv_continuous` class, `gilbrat` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `gilbrat` is:

$$f(x) = \frac{1}{x\sqrt{2\pi}} \exp\left(-\frac{1}{2}(\log(x))^2\right)$$

`gilbrat` is a special case of `lognorm` with `s=1`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gilbrat.pdf(x, loc, scale)` is identically equivalent to `gilbrat.pdf(y) / scale` with `y = (x - loc) / scale`.

## Examples

```
>>> from scipy.stats import gilbrat
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = gilbrat.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gilbrat.ppf(0.01),
... gilbrat.ppf(0.99), 100)
>>> ax.plot(x, gilbrat.pdf(x),
... 'r-', lw=5, alpha=0.6, label='gilbrat pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gilbrat()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gilbrat.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gilbrat.cdf(vals))
True
```

Generate random numbers:

```
>>> r = gilbrat.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.gompertz

`scipy.stats.gompertz` = <scipy.stats.\_continuous\_distns.gompertz\_gen object>  
 A Gompertz (or truncated Gumbel) continuous random variable.

As an instance of the `rv_continuous` class, `gompertz` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `gompertz` is:

$$f(x, c) = c \exp(x) \exp(-c(e^x - 1))$$

for  $x \geq 0, c > 0$ .

`gompertz` takes `c` as a shape parameter for `c`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gompertz.pdf(x, c, loc, scale)` is identically equivalent to `gompertz.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import gompertz
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.947
>>> mean, var, skew, kurt = gompertz.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gompertz.ppf(0.01, c),
... gompertz.ppf(0.99, c), 100)
>>> ax.plot(x, gompertz.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='gompertz pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gompertz(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gompertz.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], gompertz.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = gompertz.rvs(c, size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains <i>alpha</i> percent of the distribution

## scipy.stats.gumbel\_r

`scipy.stats.gumbel_r` = <`scipy.stats._continuous_distns.gumbel_r_gen` object>

A right-skewed Gumbel continuous random variable.

As an instance of the `rv_continuous` class, `gumbel_r` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### See also:

`gumbel_l`, `gompertz`, `genextreme`

### Notes

The probability density function for `gumbel_r` is:

$$f(x) = \exp(-(x + e^{-x}))$$

The Gumbel distribution is sometimes referred to as a type I Fisher-Tippett distribution. It is also related to the extreme value distribution, log-Weibull and Gompertz distributions.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gumbel_r.pdf(x, loc, scale)` is identically equivalent to `gumbel_r.pdf(y) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import gumbel_r
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = gumbel_r.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gumbel_r.ppf(0.01),
... gumbel_r.ppf(0.99), 100)
>>> ax.plot(x, gumbel_r.pdf(x),
... 'r-', lw=5, alpha=0.6, label='gumbel_r pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gumbel_r()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

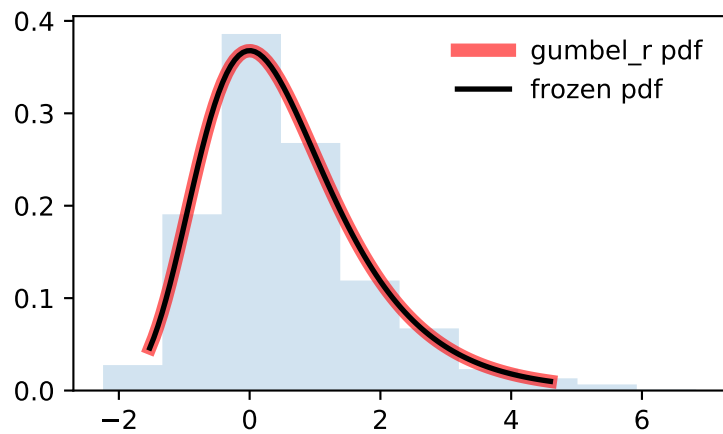

```
>>> vals = gumbel_r.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gumbel_r.cdf(vals))
True
```

Generate random numbers:

```
>>> r = gumbel_r.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.gumbel\_1

`scipy.stats.gumbel_1` = <scipy.stats.\_continuous\_distns.gumbel\_1\_gen object>

A left-skewed Gumbel continuous random variable.

As an instance of the *rv\_continuous* class, *gumbel\_1* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

*gumbel\_r*, *gompertz*, *genextreme*

## Notes

The probability density function for *gumbel\_1* is:

$$f(x) = \exp(x - e^x)$$

The Gumbel distribution is sometimes referred to as a type I Fisher-Tippett distribution. It is also related to the extreme value distribution, log-Weibull and Gompertz distributions.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `gumbel_1.pdf(x, loc, scale)` is identically equivalent to `gumbel_1.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import gumbel_l
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = gumbel_l.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gumbel_l.ppf(0.01),
... gumbel_l.ppf(0.99), 100)
>>> ax.plot(x, gumbel_l.pdf(x),
... 'r-', lw=5, alpha=0.6, label='gumbel_l pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gumbel_l()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gumbel_l.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gumbel_l.cdf(vals))
True
```

Generate random numbers:

```
>>> r = gumbel_l.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## `scipy.stats.halfcauchy`

`scipy.stats.halfcauchy = <scipy.stats._continuous_distns.halfcauchy_gen object>`  
 A Half-Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `halfcauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `halfcauchy` is:

$$f(x) = \frac{2}{\pi(1+x^2)}$$

for  $x \geq 0$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `halfcauchy.pdf(x, loc, scale)` is identically equivalent to `halfcauchy.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import halfcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = halfcauchy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halfcauchy.ppf(0.01),
... halfcauchy.ppf(0.99), 100)
>>> ax.plot(x, halfcauchy.pdf(x),
... 'r-', lw=5, alpha=0.6, label='halfcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halfcauchy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = halfcauchy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halfcauchy.cdf(vals))
True
```

Generate random numbers:

```
>>> r = halfcauchy.rvs(size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.halflogistic

`scipy.stats.halflogistic` = <`scipy.stats._continuous_distns.halflogistic_gen` object>  
 A half-logistic continuous random variable.

As an instance of the `rv_continuous` class, `halflogistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `halflogistic` is:

$$f(x) = \frac{2e^{-x}}{(1+e^{-x})^2} = \frac{1}{2} \operatorname{sech}(x/2)^2$$

for  $x \geq 0$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `halflogistic.pdf(x, loc, scale)` is identically equivalent to `halflogistic.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import halflogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = halflogistic.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halflogistic.ppf(0.01),
... halflogistic.ppf(0.99), 100)
>>> ax.plot(x, halflogistic.pdf(x),
... 'r-', lw=5, alpha=0.6, label='halflogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halflogistic()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = halflogistic.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halflogistic.cdf(vals))
True
```

Generate random numbers:

```
>>> r = halflogistic.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).

<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.halfnorm

`scipy.stats.halfnorm = <scipy.stats._continuous_distns.halfnorm_gen object>`

A half-normal continuous random variable.

As an instance of the *rv\_continuous* class, *halfnorm* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *halfnorm* is:

$$f(x) = \sqrt{2/\pi} \exp(-x^2/2)$$

for  $x \geq 0$ .

*halfnorm* is a special case of *chi* with *df*=1.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `halfnorm.pdf(x, loc, scale)` is identically equivalent to `halfnorm.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import halfnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = halfnorm.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halfnorm.ppf(0.01),
... halfnorm.ppf(0.99), 100)
>>> ax.plot(x, halfnorm.pdf(x),
... 'r-', lw=5, alpha=0.6, label='halfnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halfnorm()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

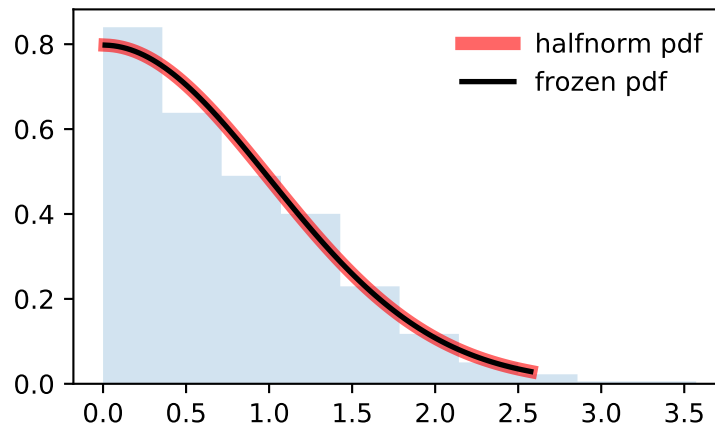

```
>>> vals = halfnorm.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halfnorm.cdf(vals))
True
```

Generate random numbers:

```
>>> r = halfnorm.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).

<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.halfgennorm

`scipy.stats.halfgennorm` = `<scipy.stats._continuous_distns.halfgennorm_gen object>`  
 The upper half of a generalized normal continuous random variable.

As an instance of the `rv_continuous` class, `halfgennorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

**gennorm**

generalized normal distribution

**expon**

exponential distribution

**halfnorm**

half normal distribution

## Notes

The probability density function for `halfgennorm` is:

$$f(x, \beta) = \frac{\beta}{\Gamma(1/\beta)} \exp(-|x|^\beta)$$

for  $x > 0$ .  $\Gamma$  is the gamma function (`scipy.special.gamma`).

`gennorm` takes `beta` as a shape parameter for  $\beta$ . For  $\beta = 1$ , it is identical to an exponential distribution. For  $\beta = 2$ , it is identical to a half normal distribution (with `scale=1/sqrt(2)`).

## References

[1]

## Examples

```
>>> from scipy.stats import halfgennorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> beta = 0.675
>>> mean, var, skew, kurt = halfgennorm.stats(beta, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halfgennorm.ppf(0.01, beta),
... halfgennorm.ppf(0.99, beta), 100)
>>> ax.plot(x, halfgennorm.pdf(x, beta),
... 'r-', lw=5, alpha=0.6, label='halfgennorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halfgennorm(beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = halfgennorm.ppf([0.001, 0.5, 0.999], beta)
>>> np.allclose([0.001, 0.5, 0.999], halfgennorm.cdf(vals, beta))
True
```

Generate random numbers:

```
>>> r = halfgennorm.rvs(beta, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.hypsecant

`scipy.stats.hypsecant = <scipy.stats._continuous_distns.hypsecant_gen object>`

A hyperbolic secant continuous random variable.

As an instance of the *rv\_continuous* class, *hypsecant* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *hypsecant* is:

$$f(x) = \frac{1}{\pi} \operatorname{sech}(x)$$

for a real number *x*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `hypsecant.pdf(x, loc, scale)` is identically equivalent to `hypsecant.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import hypsecant
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = hypsecant.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(hypsecant.ppf(0.01),
... hypsecant.ppf(0.99), 100)
>>> ax.plot(x, hypsecant.pdf(x),
... 'r-', lw=5, alpha=0.6, label='hypsecant pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = hypsecant()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = hypsecant.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], hypsecant.cdf(vals))
True
```

Generate random numbers:

```
>>> r = hypsecant.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.invgamma

`scipy.stats.invgamma` = <scipy.stats.\_continuous\_distns.invgamma\_gen object>  
 An inverted gamma continuous random variable.

As an instance of the `rv_continuous` class, `invgamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `invgamma` is:

$$f(x, a) = \frac{x^{-a-1}}{\Gamma(a)} \exp\left(-\frac{1}{x}\right)$$

for  $x \geq 0$ ,  $a > 0$ .  $\Gamma$  is the gamma function (`scipy.special.gamma`).

`invgamma` takes `a` as a shape parameter for  $a$ .

`invgamma` is a special case of `gengamma` with `c=-1`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `invgamma.pdf(x, a, loc, scale)` is identically equivalent to `invgamma.pdf(y, a) / scale` with `y = (x - loc) / scale`.

## Examples

```
>>> from scipy.stats import invgamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 4.07
>>> mean, var, skew, kurt = invgamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(invgamma.ppf(0.01, a),
... invgamma.ppf(0.99, a), 100)
>>> ax.plot(x, invgamma.pdf(x, a),
... 'r-', lw=5, alpha=0.6, label='invgamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = invgamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = invgamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], invgamma.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = invgamma.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.invgauss

`scipy.stats.invgauss = <scipy.stats._continuous_distns.invgauss_gen object>`

An inverse Gaussian continuous random variable.

As an instance of the *rv\_continuous* class, *invgauss* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *invgauss* is:

$$f(x, \mu) = \frac{1}{\sqrt{2\pi x^3}} \exp\left(-\frac{(x - \mu)^2}{2x\mu^2}\right)$$

for  $x \geq 0$  and  $\mu > 0$ .

*invgauss* takes *mu* as a shape parameter for  $\mu$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `invgauss.pdf(x, mu, loc, scale)` is identically equivalent to `invgauss.pdf(y, mu) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

When  $\mu$  is too small, evaluating the cumulative distribution function will be inaccurate due to `cdf(mu -> 0) = inf * 0`. NaNs are returned for  $\mu \leq 0.0028$ .

## Examples

```
>>> from scipy.stats import invgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mu = 0.145
>>> mean, var, skew, kurt = invgauss.stats(mu, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(invgauss.ppf(0.01, mu),
... invgauss.ppf(0.99, mu), 100)
>>> ax.plot(x, invgauss.pdf(x, mu),
... 'r-', lw=5, alpha=0.6, label='invgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = invgauss(mu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = invgauss.ppf([0.001, 0.5, 0.999], mu)
>>> np.allclose([0.001, 0.5, 0.999], invgauss.cdf(vals, mu))
True
```

Generate random numbers:

```
>>> r = invgauss.rvs(mu, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(mu, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, mu, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, mu, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, mu, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, mu, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, mu, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, mu, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, mu, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, mu, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, mu, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(mu, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(mu, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, mu, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(mu,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(mu, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(mu, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(mu, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(mu, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, mu, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.invweibull

`scipy.stats.invweibull = <scipy.stats._continuous_distns.invweibull_gen object>`  
 An inverted Weibull continuous random variable.

This distribution is also known as the Fréchet distribution or the type II extreme value distribution.

As an instance of the `rv_continuous` class, `invweibull` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `invweibull` is:

$$f(x, c) = cx^{-c-1} \exp(-x^{-c})$$

for  $x > 0, c > 0$ .

`invweibull` takes  $c$  as a shape parameter for  $c$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `invweibull.pdf(x, c, loc, scale)` is identically equivalent to `invweibull.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## References

F.R.S. de Gusmao, E.M.M Ortega and G.M. Cordeiro, “The generalized inverse Weibull distribution”, Stat. Papers, vol. 52, pp. 591-619, 2011.

## Examples

```
>>> from scipy.stats import invweibull
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 10.6
>>> mean, var, skew, kurt = invweibull.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(invweibull.ppf(0.01, c),
... invweibull.ppf(0.99, c), 100)
>>> ax.plot(x, invweibull.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='invweibull pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = invweibull(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = invweibull.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], invweibull.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = invweibull.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.johnsonsb

`scipy.stats.johnsonsb` = <`scipy.stats._continuous_distns.johnsonsb_gen` object>  
 A Johnson SB continuous random variable.

As an instance of the `rv_continuous` class, `johnsonsb` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`johnsonsu`

## Notes

The probability density function for `johnsonsb` is:

$$f(x, a, b) = \frac{b}{x(1-x)} \phi\left(a + b \log \frac{x}{1-x}\right)$$

for  $0 \leq x \leq 1$  and  $a, b > 0$ , and  $\phi$  is the normal pdf.

`johnsonsb` takes *a* and *b* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `johnsonsb.pdf(x, a, b, loc, scale)` is identically equivalent to `johnsonsb.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import johnsonsb
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 4.32, 3.18
>>> mean, var, skew, kurt = johnsonsb.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(johnsonsb.ppf(0.01, a, b),
... johnsonsb.ppf(0.99, a, b), 100)
>>> ax.plot(x, johnsonsb.pdf(x, a, b),
... 'r-', lw=5, alpha=0.6, label='johnsonsb pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = johnsonsb(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = johnsonsb.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], johnsonsb.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = johnsonsb.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, loc=0, scale=1)</code>	Probability density function.

<code>interval(alpha, a, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.johnsonsu

`scipy.stats.johnsonsu = <scipy.stats._continuous_distns.johnsonsu_gen object>`  
 A Johnson SU continuous random variable.

As an instance of the `rv_continuous` class, `johnsonsu` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`johnsonsb`

## Notes

The probability density function for `johnsonsu` is:

$$f(x, a, b) = \frac{b}{\sqrt{x^2 + 1}} \phi(a + b \log(x + \sqrt{x^2 + 1}))$$

for all  $x, a, b > 0$ , and  $\phi$  is the normal pdf.

`johnsonsu` takes  $a$  and  $b$  as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `johnsonsu.pdf(x, a, b, loc, scale)` is identically equivalent to `johnsonsu.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import johnsonsu
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 2.55, 2.25
>>> mean, var, skew, kurt = johnsonsu.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(johnsonsu.ppf(0.01, a, b),
... johnsonsu.ppf(0.99, a, b), 100)
>>> ax.plot(x, johnsonsu.pdf(x, a, b),
... 'r-', lw=5, alpha=0.6, label='johnsonsu pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = johnsonsu(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = johnsonsu.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], johnsonsu.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = johnsonsu.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).

<code>entropy(a, b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, b, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.kappa4

`scipy.stats.kappa4 = <scipy.stats._continuous_distns.kappa4_gen object>`

Kappa 4 parameter distribution.

As an instance of the `rv_continuous` class, `kappa4` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for kappa4 is:

$$f(x, h, k) = (1 - kx)^{1/k-1} (1 - h(1 - kx)^{1/k})^{1/h-1}$$

if *h* and *k* are not equal to 0.

If *h* or *k* are zero then the pdf can be simplified:

*h* = 0 and *k* != 0:

$$\text{kappa4.pdf}(x, h, k) = (1.0 - k*x) ** (1.0/k - 1.0) * \exp(-(1.0 - k*x) ** (1.0/k))$$

*h* != 0 and *k* = 0:

```
kappa4.pdf(x, h, k) = exp(-x) * (1.0 - h*exp(-x)) ** (1.0/h - 1.0)
```

$h = 0$  and  $k = 0$ :

```
kappa4.pdf(x, h, k) = exp(-x) * exp(-exp(-x))
```

`kappa4` takes  $h$  and  $k$  as shape parameters.

The `kappa4` distribution returns other distributions when certain  $h$  and  $k$  values are used.

h	k=0.0	k=1.0	-inf<=k<=inf
-1.0	Logistic logistic(x)		Generalized Logistic(1)
0.0	Gumbel gumbel_r(x)	Reverse Exponential(2)	Generalized Extreme Value genextreme(x, k)
1.0	Exponential expon(x)	Uniform uniform(x)	Generalized Pareto genpareto(x, -k)

- (1) There are at least five generalized logistic distributions. Four are described here: [https://en.wikipedia.org/wiki/Generalized\\_logistic\\_distribution](https://en.wikipedia.org/wiki/Generalized_logistic_distribution) The “fifth” one is the one `kappa4` should match which currently isn’t implemented in `scipy`: [https://en.wikipedia.org/wiki/Talk:Generalized\\_logistic\\_distribution](https://en.wikipedia.org/wiki/Talk:Generalized_logistic_distribution) [https://www.mathwave.com/help/easyfit/html/analyses/distributions/gen\\_logistic.html](https://www.mathwave.com/help/easyfit/html/analyses/distributions/gen_logistic.html)
- (2) This distribution is currently not in `scipy`.

C. Winchester, “On Estimation of the Four-Parameter Kappa Distribution”, A Thesis Submitted to Dalhousie University, Halifax, Nova Scotia, (March 2000). <http://www.nlc-bnc.ca/obj/s4/f2/dsk2/ftp01/MQ57336.pdf>

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `kappa4.pdf(x, h, k, loc, scale)` is identically equivalent to `kappa4.pdf(y, h, k) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import kappa4
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> h, k = 0.1, 0
>>> mean, var, skew, kurt = kappa4.stats(h, k, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(kappa4.ppf(0.01, h, k),
... kappa4.ppf(0.99, h, k), 100)
>>> ax.plot(x, kappa4.pdf(x, h, k),
... 'r-', lw=5, alpha=0.6, label='kappa4 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = kappa4(h, k)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = kappa4.ppf([0.001, 0.5, 0.999], h, k)
>>> np.allclose([0.001, 0.5, 0.999], kappa4.cdf(vals, h, k))
True
```

Generate random numbers:

```
>>> r = kappa4.rvs(h, k, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(h, k, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, h, k, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, h, k, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, h, k, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, h, k, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, h, k, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, h, k, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, h, k, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, h, k, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, h, k, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(h, k, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(h, k, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, h, k, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(h, k), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(h, k, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(h, k, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(h, k, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(h, k, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, h, k, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.kappa3

`scipy.stats.kappa3 = <scipy.stats._continuous_distns.kappa3_gen object>`

Kappa 3 parameter distribution.

As an instance of the *rv\_continuous* class, *kappa3* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *kappa3* is:

$$f(x, a) = a(a + x^a)^{-(a+1)/a}$$

for  $x > 0$  and  $a > 0$ .

*kappa3* takes *a* as a shape parameter for *a*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `kappa3.pdf(x, a, loc, scale)` is identically equivalent to `kappa3.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import kappa3
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 1
>>> mean, var, skew, kurt = kappa3.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(kappa3.ppf(0.01, a),
... kappa3.ppf(0.99, a), 100)
>>> ax.plot(x, kappa3.pdf(x, a),
... 'r-', lw=5, alpha=0.6, label='kappa3 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = kappa3(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = kappa3.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], kappa3.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = kappa3.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.ksone

`scipy.stats.ksone = <scipy.stats._continuous_distns.ksone_gen object>`  
 General Kolmogorov-Smirnov one-sided test.

This is the distribution of the one-sided Kolmogorov-Smirnov (KS) statistics  $D_n^+$  and  $D_n^-$  for a finite sample size  $n$  (the shape parameter).

As an instance of the `rv_continuous` class, `ksone` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`kstwobign`, `kstest`

## Notes

$D_n^+$  and  $D_n^-$  are given by

$$D_n^+ = \sup_x (F_n(x) - F(x)),$$

$$D_n^- = \sup_x (F(x) - F_n(x)),$$

where  $F$  is a CDF and  $F_n$  is an empirical CDF. `ksone` describes the distribution under the null hypothesis of the KS test that the empirical CDF corresponds to  $n$  i.i.d. random variates with CDF  $F$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `ksone.pdf(x, n, loc, scale)` is identically equivalent to `ksone.pdf(y, n) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## References

[1]

## Examples

```
>>> from scipy.stats import ksone
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> n = 1e+03
>>> mean, var, skew, kurt = ksone.stats(n, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(ksone.ppf(0.01, n),
... ksone.ppf(0.99, n), 100)
>>> ax.plot(x, ksone.pdf(x, n),
... 'r-', lw=5, alpha=0.6, label='ksone pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = ksone(n)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = ksone.ppf([0.001, 0.5, 0.999], n)
>>> np.allclose([0.001, 0.5, 0.999], ksone.cdf(vals, n))
True
```

Generate random numbers:

```
>>> r = ksone.rvs(n, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>std(n, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, n, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.kstwobign

`scipy.stats.kstwobign = <scipy.stats._continuous_distns.kstwobign_gen object>`  
 Kolmogorov-Smirnov two-sided test for large *N*.

This is the asymptotic distribution of the two-sided Kolmogorov-Smirnov statistic  $\sqrt{n}D_n$  that measures the maximum absolute distance of the theoretical CDF from the empirical CDF (see *kstest*).

As an instance of the *rv\_continuous* class, *kstwobign* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

*ksone*, *kstest*

## Notes

$\sqrt{n}D_n$  is given by

$$D_n = \sup_x |F_n(x) - F(x)|$$

where *F* is a CDF and *F<sub>n</sub>* is an empirical CDF. *kstwobign* describes the asymptotic distribution (i.e. the limit of  $\sqrt{n}D_n$ ) under the null hypothesis of the KS test that the empirical CDF corresponds to i.i.d. random variates with CDF *F*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `kstwobign.pdf(x, loc, scale)` is identically equivalent to `kstwobign.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## References

## Examples

```
>>> from scipy.stats import kstwobign
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = kstwobign.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(kstwobign.ppf(0.01),
... kstwobign.ppf(0.99), 100)
>>> ax.plot(x, kstwobign.pdf(x),
... 'r-', lw=5, alpha=0.6, label='kstwobign pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = kstwobign()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = kstwobign.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], kstwobign.cdf(vals))
True
```

Generate random numbers:

```
>>> r = kstwobign.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

## scipy.stats.laplace

`scipy.stats.laplace` = <scipy.stats.\_continuous\_distns.laplace\_gen object>  
 A Laplace continuous random variable.

As an instance of the `rv_continuous` class, `laplace` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `laplace` is

$$f(x) = \frac{1}{2} \exp(-|x|)$$

for a real number  $x$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `laplace.pdf(x, loc, scale)` is identically equivalent to `laplace.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import laplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = laplace.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(laplace.ppf(0.01),
... laplace.ppf(0.99), 100)
>>> ax.plot(x, laplace.pdf(x),
... 'r-', lw=5, alpha=0.6, label='laplace pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = laplace()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = laplace.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], laplace.cdf(vals))
True
```

Generate random numbers:

```
>>> r = laplace.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).

<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.levy

`scipy.stats.levy = <scipy.stats._continuous_distns.levy_gen object>`  
 A Levy continuous random variable.

As an instance of the `rv_continuous` class, `levy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`levy_stable`, `levy_l`

## Notes

The probability density function for `levy` is:

$$f(x) = \frac{1}{\sqrt{2\pi x^3}} \exp\left(-\frac{1}{2x}\right)$$

for  $x \geq 0$ .

This is the same as the Levy-stable distribution with  $a = 1/2$  and  $b = 1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `levy.pdf(x, loc, scale)` is identically equivalent to `levy.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import levy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = levy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(levy.ppf(0.01),
... levy.ppf(0.99), 100)
>>> ax.plot(x, levy.pdf(x),
... 'r-', lw=5, alpha=0.6, label='levy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = levy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = levy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], levy.cdf(vals))
True
```

Generate random numbers:

```
>>> r = levy.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).

<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.levy\_l

`scipy.stats.levy_l = <scipy.stats._continuous_distns.levy_l_gen object>`

A left-skewed Levy continuous random variable.

As an instance of the `rv_continuous` class, `levy_l` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`levy`, `levy_stable`

## Notes

The probability density function for `levy_l` is:

$$f(x) = \frac{1}{|x|\sqrt{2\pi|x|}} \exp\left(-\frac{1}{2|x|}\right)$$

for  $x \leq 0$ .

This is the same as the Levy-stable distribution with  $a = 1/2$  and  $b = -1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `levy_l.pdf(x, loc, scale)` is identically equivalent to `levy_l.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import levy_l
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = levy_l.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(levy_l.ppf(0.01),
... levy_l.ppf(0.99), 100)
>>> ax.plot(x, levy_l.pdf(x),
... 'r-', lw=5, alpha=0.6, label='levy_l pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = levy_l()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = levy_l.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], levy_l.cdf(vals))
True
```

Generate random numbers:

```
>>> r = levy_l.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.levy\_stable

`scipy.stats.levy_stable = <scipy.stats._continuous_distns.levy_stable_gen object>`  
 A Levy-stable continuous random variable.

As an instance of the `rv_continuous` class, `levy_stable` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

`levy`, `levy_l`

## Notes

The distribution for `levy_stable` has characteristic function:

$$\varphi(t, \alpha, \beta, c, \mu) = e^{it\mu - |ct|^\alpha (1 - i\beta \operatorname{sign}(t)\Phi(\alpha, t))}$$

where:

$$\Phi = \begin{cases} \tan\left(\frac{\pi\alpha}{2}\right) & \alpha \neq 1 \\ -\frac{2}{\pi} \log|t| & \alpha = 1 \end{cases}$$

The probability density function for `levy_stable` is:

$$f(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \varphi(t) e^{-ixt} dt$$

where  $-\infty < t < \infty$ . This integral does not have a known closed form.

For evaluation of pdf we use either Zolotarev  $S_0$  parameterization with integration, direct integration of standard parameterization of characteristic function or FFT of characteristic function. If set to other than `None` and if number of points is greater than `levy_stable.pdf_fft_min_points_threshold` (defaults to `None`) we use FFT otherwise we use one of the other methods.

The default method is 'best' which uses Zolotarev's method if `alpha = 1` and integration of characteristic function otherwise. The default method can be changed by setting `levy_stable.pdf_default_method` to either 'zolotarev', 'quadrature' or 'best'.

To increase accuracy of FFT calculation one can specify `levy_stable.pdf_fft_grid_spacing` (defaults to 0.001) and `pdf_fft_n_points_two_power` (defaults to a value that covers the input range \* 4). Setting `pdf_fft_n_points_two_power` to 16 should be sufficiently accurate in most cases at the expense of CPU time.

For evaluation of cdf we use Zolotarev  $S_0$  parameterization with integration or integral of the pdf FFT interpolated spline. The settings affecting FFT calculation are the same as for pdf calculation. Setting the threshold to `None` (default) will disable FFT. For cdf calculations the Zolotarev method is superior in accuracy, so FFT is disabled by default.

Fitting estimate uses quantile estimation method in [MC]. MLE estimation of parameters in fit method uses this quantile estimate initially. Note that MLE doesn't always converge if using FFT for pdf calculations; so it's best that `pdf_fft_min_points_threshold` is left unset.

**Warning:** For pdf calculations implementation of Zolotarev is unstable for values where `alpha = 1` and `beta != 0`. In this case the quadrature method is recommended. FFT calculation is also considered experimental.

For cdf calculations FFT calculation is considered experimental. Use Zolotarev's method instead (default).

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `levy_stable.pdf(x, alpha, beta, loc, scale)` is identically equivalent to `levy_stable.pdf(y, alpha, beta) / scale` with `y = (x - loc) / scale`.

## Examples

```
>>> from scipy.stats import levy_stable
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> alpha, beta = 1.8, -0.5
>>> mean, var, skew, kurt = levy_stable.stats(alpha, beta, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(levy_stable.ppf(0.01, alpha, beta),
... levy_stable.ppf(0.99, alpha, beta), 100)
>>> ax.plot(x, levy_stable.pdf(x, alpha, beta),
... 'r-', lw=5, alpha=0.6, label='levy_stable pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = levy_stable(alpha, beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = levy_stable.ppf([0.001, 0.5, 0.999], alpha, beta)
>>> np.allclose([0.001, 0.5, 0.999], levy_stable.cdf(vals, alpha, beta))
True
```

Generate random numbers:

```
>>> r = levy_stable.rvs(alpha, beta, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.logistic

`scipy.stats.logistic` = <`scipy.stats._continuous_distns.logistic_gen` object>  
 A logistic (or Sech-squared) continuous random variable.

As an instance of the `rv_continuous` class, `logistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `logistic` is:

$$f(x) = \frac{\exp(-x)}{(1 + \exp(-x))^2}$$

`logistic` is a special case of `genlogistic` with `c=1`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `logistic.pdf(x, loc, scale)` is identically equivalent to `logistic.pdf(y) / scale` with `y = (x - loc) / scale`.

## Examples

```
>>> from scipy.stats import logistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = logistic.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(logistic.ppf(0.01),
... logistic.ppf(0.99), 100)
>>> ax.plot(x, logistic.pdf(x),
... 'r-', lw=5, alpha=0.6, label='logistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = logistic()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = logistic.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], logistic.cdf(vals))
True
```

Generate random numbers:

```
>>> r = logistic.rvs(size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

## scipy.stats.loggamma

`scipy.stats.loggamma` = <`scipy.stats._continuous_distns.loggamma_gen` object>

A log gamma continuous random variable.

As an instance of the `rv_continuous` class, `loggamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `loggamma` is:

$$f(x, c) = \frac{\exp(cx - \exp(x))}{\Gamma(c)}$$

for all  $x, c > 0$ . Here,  $\Gamma$  is the gamma function (`scipy.special.gamma`).

`loggamma` takes `c` as a shape parameter for `c`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `loggamma.pdf(x, c, loc, scale)` is identically equivalent to `loggamma.pdf(y, c) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import loggamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.414
>>> mean, var, skew, kurt = loggamma.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(loggamma.ppf(0.01, c),
... loggamma.ppf(0.99, c), 100)
>>> ax.plot(x, loggamma.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='loggamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = loggamma(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

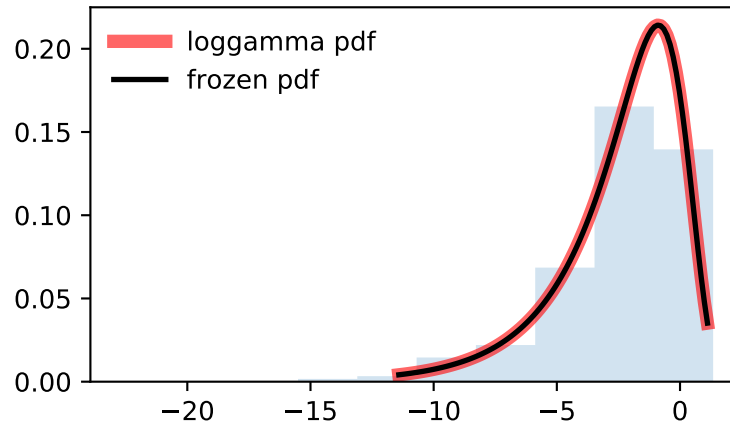

```
>>> vals = loggamma.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], loggamma.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = loggamma.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).

<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.loglaplace

`scipy.stats.loglaplace` = <`scipy.stats._continuous_distns.loglaplace_gen` object>  
 A log-Laplace continuous random variable.

As an instance of the `rv_continuous` class, `loglaplace` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `loglaplace` is:

$$f(x, c) = \begin{cases} \frac{c}{2}x^{c-1} & \text{for } 0 < x < 1 \\ \frac{c}{2}x^{-c-1} & \text{for } x \geq 1 \end{cases}$$

for  $c > 0$ .

`loglaplace` takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `loglaplace.pdf(x, c, loc, scale)` is identically equivalent to `loglaplace.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## References

T.J. Kozubowski and K. Podgorski, “A log-Laplace growth rate model”, The Mathematical Scientist, vol. 28, pp. 49-60, 2003.

## Examples

```
>>> from scipy.stats import loglaplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 3.25
>>> mean, var, skew, kurt = loglaplace.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(loglaplace.ppf(0.01, c),
... loglaplace.ppf(0.99, c), 100)
>>> ax.plot(x, loglaplace.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='loglaplace pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = loglaplace(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = loglaplace.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], loglaplace.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = loglaplace.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.lognorm

`scipy.stats.lognorm` = <scipy.stats.\_continuous\_distns.lognorm\_gen object>  
 A lognormal continuous random variable.

As an instance of the `rv_continuous` class, `lognorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `lognorm` is:

$$f(x, s) = \frac{1}{sx\sqrt{2\pi}} \exp\left(-\frac{\log^2(x)}{2s^2}\right)$$

for  $x > 0, s > 0$ .

`lognorm` takes  $s$  as a shape parameter for  $s$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `lognorm.pdf(x, s, loc, scale)` is identically equivalent to `lognorm.pdf(y, s) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

A common parametrization for a lognormal random variable  $Y$  is in terms of the mean,  $\mu$ , and standard deviation,  $\sigma$ , of the unique normally distributed random variable  $X$  such that  $\exp(X) = Y$ . This parametrization corresponds to setting  $s = \sigma$  and  $\text{scale} = \exp(\mu)$ .

## Examples

```
>>> from scipy.stats import lognorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> s = 0.954
>>> mean, var, skew, kurt = lognorm.stats(s, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(lognorm.ppf(0.01, s),
... lognorm.ppf(0.99, s), 100)
>>> ax.plot(x, lognorm.pdf(x, s),
... 'r-', lw=5, alpha=0.6, label='lognorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = lognorm(s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = lognorm.ppf([0.001, 0.5, 0.999], s)
>>> np.allclose([0.001, 0.5, 0.999], lognorm.cdf(vals, s))
True
```

Generate random numbers:

```
>>> r = lognorm.rvs(s, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(s, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, s, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, s, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, s, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, s, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, s, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, s, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, s, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, s, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, s, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(s, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(s, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, s, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(s,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(s, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(s, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(s, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(s, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, s, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.lomax

`scipy.stats.lomax` = <scipy.stats.\_continuous\_distns.lomax\_gen object>

A Lomax (Pareto of the second kind) continuous random variable.

As an instance of the *rv\_continuous* class, *lomax* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *lomax* is:

$$f(x, c) = \frac{c}{(1+x)^{c+1}}$$

for  $x \geq 0, c > 0$ .

*lomax* takes *c* as a shape parameter for *c*.

*lomax* is a special case of *pareto* with `loc=-1.0`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `lomax.pdf(x, c, loc, scale)` is identically equivalent to `lomax.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import lomax
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 1.88
>>> mean, var, skew, kurt = lomax.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(lomax.ppf(0.01, c),
... lomax.ppf(0.99, c), 100)
>>> ax.plot(x, lomax.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='lomax pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = lomax(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = lomax.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], lomax.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = lomax.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but $\text{sf}$ is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of $\text{cdf}$ — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of $\text{sf}$ ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order $n$
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## `scipy.stats.maxwell`

`scipy.stats.maxwell` = `<scipy.stats._continuous_distns.maxwell_gen object>`  
 A Maxwell continuous random variable.

As an instance of the `rv_continuous` class, `maxwell` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

A special case of a `chi` distribution, with `df=3`, `loc=0.0`, and given `scale = a`, where `a` is the parameter used in the Mathworld description [1].

The probability density function for `maxwell` is:

$$f(x) = \sqrt{2/\pi} x^2 \exp(-x^2/2)$$

for  $x \geq 0$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `maxwell.pdf(x, loc, scale)` is identically equivalent to `maxwell.pdf(y) / scale` with `y = (x - loc) / scale`.

## References

[1]

## Examples

```
>>> from scipy.stats import maxwell
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = maxwell.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(maxwell.ppf(0.01),
... maxwell.ppf(0.99), 100)
>>> ax.plot(x, maxwell.pdf(x),
... 'r-', lw=5, alpha=0.6, label='maxwell pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = maxwell()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = maxwell.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], maxwell.cdf(vals))
True
```

Generate random numbers:

```
>>> r = maxwell.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.mielke

`scipy.stats.mielke` = <`scipy.stats._continuous_distns.mielke_gen` object>

A Mielke Beta-Kappa continuous random variable.

As an instance of the `rv_continuous` class, `mielke` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `mielke` is:

$$f(x, k, s) = \frac{kx^{k-1}}{(1+x^s)^{1+k/s}}$$

for  $x \geq 0$  and  $k, s > 0$ .

`mielke` takes *k* and *s* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `mielke.pdf(x, k, s, loc, scale)` is identically equivalent to `mielke.pdf(y, k, s) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## References

[1]

## Examples

```
>>> from scipy.stats import mielke
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> k, s = 10.4, 4.6
>>> mean, var, skew, kurt = mielke.stats(k, s, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(mielke.ppf(0.01, k, s),
... mielke.ppf(0.99, k, s), 100)
>>> ax.plot(x, mielke.pdf(x, k, s),
... 'r-', lw=5, alpha=0.6, label='mielke pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = mielke(k, s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = mielke.ppf([0.001, 0.5, 0.999], k, s)
>>> np.allclose([0.001, 0.5, 0.999], mielke.cdf(vals, k, s))
True
```

Generate random numbers:

```
>>> r = mielke.rvs(k, s, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.moyal

`scipy.stats.moyal = <scipy.stats._continuous_distns.moyal_gen object>`  
 A Moyal continuous random variable.

As an instance of the `rv_continuous` class, `moyal` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `moyal` is:

$$f(x) = \exp(-(x + \exp(-x))/2) / \sqrt{2\pi}$$

for a real number  $x$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `moyal.pdf(x, loc, scale)` is identically equivalent to `moyal.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

This distribution has utility in high-energy physics and radiation detection. It describes the energy loss of a charged relativistic particle due to ionization of the medium [1]. It also provides an approximation for the Landau distribution. For an in depth description see [2]. For additional description, see [3].

## References

New in version 1.1.0.

[1], [2], [3]

## Examples

```
>>> from scipy.stats import moyal
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = moyal.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(moyal.ppf(0.01),
... moyal.ppf(0.99), 100)
>>> ax.plot(x, moyal.pdf(x),
... 'r-', lw=5, alpha=0.6, label='moyal pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = moyal()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = moyal.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], moyal.cdf(vals))
True
```

Generate random numbers:

```
>>> r = moyal.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.nakagami

`scipy.stats.nakagami` = <`scipy.stats._continuous_distns.nakagami_gen` object>

A Nakagami continuous random variable.

As an instance of the `rv_continuous` class, `nakagami` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `nakagami` is:

$$f(x, \nu) = \frac{2\nu^\nu}{\Gamma(\nu)} x^{2\nu-1} \exp(-\nu x^2)$$

for  $x \geq 0, \nu > 0$ .

`nakagami` takes `nu` as a shape parameter for  $\nu$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `nakagami.pdf(x, nu, loc, scale)` is identically equivalent to `nakagami.pdf(y, nu) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import nakagami
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> nu = 4.97
>>> mean, var, skew, kurt = nakagami.stats(nu, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(nakagami.ppf(0.01, nu),
... nakagami.ppf(0.99, nu), 100)
>>> ax.plot(x, nakagami.pdf(x, nu),
... 'r-', lw=5, alpha=0.6, label='nakagami pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = nakagami(nu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = nakagami.ppf([0.001, 0.5, 0.999], nu)
>>> np.allclose([0.001, 0.5, 0.999], nakagami.cdf(vals, nu))
True
```

Generate random numbers:

```
>>> r = nakagami.rvs(nu, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(nu, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, nu, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, nu, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, nu, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, nu, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, nu, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, nu, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, nu, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, nu, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, nu, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(nu, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(nu, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, nu, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(nu,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(nu, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(nu, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(nu, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(nu, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, nu, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.ncx2

`scipy.stats.ncx2 = <scipy.stats._continuous_distns.ncx2_gen object>`

A non-central chi-squared continuous random variable.

As an instance of the `rv_continuous` class, `ncx2` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `ncx2` is:

$$f(x, k, \lambda) = \frac{1}{2} \exp(-(\lambda + x)/2) (x/\lambda)^{(k-2)/4} I_{(k-2)/2}(\sqrt{\lambda x})$$

for  $x \geq 0$  and  $k, \lambda > 0$ .  $k$  specifies the degrees of freedom (denoted `df` in the implementation) and  $\lambda$  is the non-centrality parameter (denoted `nc` in the implementation).  $I_\nu$  denotes the modified Bessel function of first order of degree  $\nu$  (`scipy.special.iv`).

`ncx2` takes `df` and `nc` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `ncx2.pdf(x, df, nc, loc, scale)` is identically equivalent to `ncx2.pdf(y, df, nc) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import ncx2
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> df, nc = 21, 1.06
>>> mean, var, skew, kurt = ncx2.stats(df, nc, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(ncx2.ppf(0.01, df, nc),
... ncx2.ppf(0.99, df, nc), 100)
>>> ax.plot(x, ncx2.pdf(x, df, nc),
... 'r-', lw=5, alpha=0.6, label='ncx2 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = ncx2(df, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = ncx2.ppf([0.001, 0.5, 0.999], df, nc)
>>> np.allclose([0.001, 0.5, 0.999], ncx2.cdf(vals, df, nc))
True
```

Generate random numbers:

```
>>> r = ncx2.rvs(df, nc, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(df, nc, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, df, nc, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, df, nc, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, df, nc, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, df, nc, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, df, nc, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, df, nc, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, df, nc, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, df, nc, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, df, nc, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(df, nc, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(df, nc, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, df, nc, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(df, nc), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(df, nc, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(df, nc, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(df, nc, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(df, nc, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, df, nc, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.ncf

`scipy.stats.ncf = <scipy.stats._continuous_distns.ncf_gen object>`

A non-central F distribution continuous random variable.

As an instance of the `rv_continuous` class, `ncf` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `ncf` is:

$$f(x, n_1, n_2, \lambda) = \exp\left(\frac{\lambda}{2} + \lambda n_1 \frac{x}{2(n_1 x + n_2)}\right) n_1^{n_1/2} n_2^{n_2/2} x^{n_1/2-1} \\ (n_2 + n_1 x)^{-(n_1+n_2)/2} \gamma(n_1/2) \gamma(1 + n_2/2) \\ \frac{L_{n_2/2}^{n_1/2-1}(-\lambda v_1 \frac{x}{2(v_1 x + v_2)})}{B(v_1/2, v_2/2) \gamma(\frac{v_1+v_2}{2})}$$

for  $n_1 > 1$ ,  $n_2, \lambda > 0$ . Here  $n_1$  is the degrees of freedom in the numerator,  $n_2$  the degrees of freedom in the denominator,  $\lambda$  the non-centrality parameter,  $\gamma$  is the logarithm of the Gamma function,  $L_n^k$  is a generalized Laguerre polynomial and  $B$  is the beta function.

`ncf` takes `df1`, `df2` and `nc` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `ncf.pdf(x, dfn, dfd, nc, loc, scale)` is identically equivalent to `ncf.pdf(y, dfn, dfd, nc) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import ncf
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> dfn, dfd, nc = 27, 27, 0.416
>>> mean, var, skew, kurt = ncf.stats(dfn, dfd, nc, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(ncf.ppf(0.01, dfn, dfd, nc),
... ncf.ppf(0.99, dfn, dfd, nc), 100)
>>> ax.plot(x, ncf.pdf(x, dfn, dfd, nc),
... 'r-', lw=5, alpha=0.6, label='ncf pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = ncf(dfn, dfd, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = ncf.ppf([0.001, 0.5, 0.999], dfn, dfd, nc)
>>> np.allclose([0.001, 0.5, 0.999], ncf.cdf(vals, dfn, dfd, nc))
True
```

Generate random numbers:

```
>>> r = ncf.rvs(dfn, dfd, nc, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(dfn, dfd, nc, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, dfn, dfd, nc, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, dfn, dfd, nc, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, dfn, dfd, nc, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, dfn, dfd, nc, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, dfn, dfd, nc, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, dfn, dfd, nc, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, dfn, dfd, nc, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, dfn, dfd, nc, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, dfn, dfd, nc, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(dfn, dfd, nc, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(dfn, dfd, nc, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, dfn, dfd, nc, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(dfn, dfd, nc), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(dfn, dfd, nc, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(dfn, dfd, nc, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(dfn, dfd, nc, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(dfn, dfd, nc, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, dfn, dfd, nc, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.nct

`scipy.stats.nct` = `<scipy.stats._continuous_distns.nct_gen object>`  
 A non-central Student's *t* continuous random variable.

As an instance of the `rv_continuous` class, `nct` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

If  $Y$  is a standard normal random variable and  $V$  is an independent chi-square random variable (*chi2*) with  $k$  degrees of freedom, then

$$X = \frac{Y + c}{\sqrt{V/k}}$$

has a non-central Student's t distribution on the real line. The degrees of freedom parameter  $k$  (denoted `df` in the implementation) satisfies  $k > 0$  and the noncentrality parameter  $c$  (denoted `nct` in the implementation) is a real number.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `nct.pdf(x, df, nc, loc, scale)` is identically equivalent to `nct.pdf(y, df, nc) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import nct
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> df, nc = 14, 0.24
>>> mean, var, skew, kurt = nct.stats(df, nc, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(nct.ppf(0.01, df, nc),
... nct.ppf(0.99, df, nc), 100)
>>> ax.plot(x, nct.pdf(x, df, nc),
... 'r-', lw=5, alpha=0.6, label='nct pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = nct(df, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = nct.ppf([0.001, 0.5, 0.999], df, nc)
>>> np.allclose([0.001, 0.5, 0.999], nct.cdf(vals, df, nc))
True
```

Generate random numbers:

```
>>> r = nct.rvs(df, nc, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(df, nc, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, df, nc, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, df, nc, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, df, nc, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, df, nc, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, df, nc, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, df, nc, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, df, nc, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, df, nc, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, df, nc, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(df, nc, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(df, nc, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, df, nc, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(df, nc), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(df, nc, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(df, nc, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(df, nc, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(df, nc, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, df, nc, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.norm

`scipy.stats.norm = <scipy.stats._continuous_distns.norm_gen object>`

A normal continuous random variable.

The location (*loc*) keyword specifies the mean. The scale (*scale*) keyword specifies the standard deviation.

As an instance of the *rv\_continuous* class, *norm* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *norm* is:

$$f(x) = \frac{\exp(-x^2/2)}{\sqrt{2\pi}}$$

for a real number *x*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `norm.pdf(x, loc, scale)` is identically equivalent to `norm.pdf(y) / scale` with `y = (x - loc) / scale`.

## Examples

```
>>> from scipy.stats import norm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = norm.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(norm.ppf(0.01),
... norm.ppf(0.99), 100)
>>> ax.plot(x, norm.pdf(x),
... 'r-', lw=5, alpha=0.6, label='norm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = norm()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = norm.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], norm.cdf(vals))
True
```

Generate random numbers:

```
>>> r = norm.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## `scipy.stats.norminvgauss`

```
scipy.stats.norminvgauss = <scipy.stats._continuous_distns.norminvgauss_gen object>
 A Normal Inverse Gaussian continuous random variable.
```

As an instance of the `rv_continuous` class, `norminvgauss` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `norminvgauss` is:

$$f(x, a, b) = (a \exp(\sqrt{a^2 - b^2} + bx)) / (\pi \sqrt{1 + x^2} K_1(a \sqrt{1 + x^2}))$$

where  $x$  is a real number, the parameter  $a$  is the tail heaviness and  $b$  is the asymmetry parameter satisfying  $a > 0$  and  $|b| \leq a$ .  $K_1$  is the modified Bessel function of second kind (`scipy.special.k1`).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `norminvgauss.pdf(x, a, b, loc, scale)` is identically equivalent to `norminvgauss.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

A normal inverse Gaussian random variable  $Y$  with parameters  $a$  and  $b$  can be expressed as a normal mean-variance mixture:  $Y = b * V + \text{sqrt}(V) * X$  where  $X$  is `norm(0,1)` and  $V$  is `invgauss(mu=1/sqrt(a**2 - b**2))`. This representation is used to generate random variates.

## Examples

```
>>> from scipy.stats import norminvgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 1, 0.5
>>> mean, var, skew, kurt = norminvgauss.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(norminvgauss.ppf(0.01, a, b),
... norminvgauss.ppf(0.99, a, b), 100)
>>> ax.plot(x, norminvgauss.pdf(x, a, b),
... 'r-', lw=5, alpha=0.6, label='norminvgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = norminvgauss(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = norminvgauss.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], norminvgauss.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = norminvgauss.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## scipy.stats.pareto

`scipy.stats.pareto = <scipy.stats._continuous_distns.pareto_gen object>`

A Pareto continuous random variable.

As an instance of the `rv_continuous` class, `pareto` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `pareto` is:

$$f(x, b) = \frac{b}{x^{b+1}}$$

for  $x \geq 1, b > 0$ .

`pareto` takes `b` as a shape parameter for  $b$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `pareto.pdf(x, b, loc, scale)` is identically equivalent to `pareto.pdf(y, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import pareto
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> b = 2.62
>>> mean, var, skew, kurt = pareto.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(pareto.ppf(0.01, b),
... pareto.ppf(0.99, b), 100)
>>> ax.plot(x, pareto.pdf(x, b),
... 'r-', lw=5, alpha=0.6, label='pareto pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = pareto(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = pareto.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], pareto.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = pareto.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.

<code>median(b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.pearson3

`scipy.stats.pearson3 = <scipy.stats._continuous_distns.pearson3_gen object>`  
 A pearson type III continuous random variable.

As an instance of the `rv_continuous` class, `pearson3` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `pearson3` is:

$$f(x, skew) = \frac{|\beta|}{\Gamma(\alpha)} (\beta(x - \zeta))^{\alpha-1} \exp(-\beta(x - \zeta))$$

where:

$$\beta = \frac{2}{skewstddev} \alpha = (stddev\beta)^2 \zeta = loc - \frac{\alpha}{\beta}$$

$\Gamma$  is the gamma function (`scipy.special.gamma`). `pearson3` takes `skew` as a shape parameter for `skew`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `pearson3.pdf(x, skew, loc, scale)` is identically equivalent to `pearson3.pdf(y, skew) / scale` with `y = (x - loc) / scale`.

## Examples

```
>>> from scipy.stats import pearson3
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> skew = 0.1
>>> mean, var, skew, kurt = pearson3.stats(skew, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(pearson3.ppf(0.01, skew),
... pearson3.ppf(0.99, skew), 100)
>>> ax.plot(x, pearson3.pdf(x, skew),
... 'r-', lw=5, alpha=0.6, label='pearson3 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = pearson3(skew)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = pearson3.ppf([0.001, 0.5, 0.999], skew)
>>> np.allclose([0.001, 0.5, 0.999], pearson3.cdf(vals, skew))
True
```

Generate random numbers:

```
>>> r = pearson3.rvs(skew, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(skew, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, skew, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, skew, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, skew, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, skew, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, skew, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, skew, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, skew, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, skew, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, skew, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(skew, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(skew, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, skew, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(skew,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(skew, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(skew, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(skew, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(skew, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, skew, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.powerlaw

`scipy.stats.powerlaw = <scipy.stats._continuous_distns.powerlaw_gen object>`  
 A power-function continuous random variable.

As an instance of the `rv_continuous` class, `powerlaw` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `powerlaw` is:

$$f(x, a) = ax^{a-1}$$

for  $0 \leq x \leq 1, a > 0$ .

`powerlaw` takes *a* as a shape parameter for *a*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `powerlaw.pdf(x, a, loc, scale)` is identically equivalent to `powerlaw.pdf(y, a) / scale` with `y = (x - loc) / scale`.

`powerlaw` is a special case of `beta` with `b=1`.

## Examples

```
>>> from scipy.stats import powerlaw
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 1.66
>>> mean, var, skew, kurt = powerlaw.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(powerlaw.ppf(0.01, a),
... powerlaw.ppf(0.99, a), 100)
>>> ax.plot(x, powerlaw.pdf(x, a),
... 'r-', lw=5, alpha=0.6, label='powerlaw pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = powerlaw(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = powerlaw.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], powerlaw.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = powerlaw.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.powerlognorm

`scipy.stats.powerlognorm = <scipy.stats._continuous_distns.powerlognorm_gen object>`  
 A power log-normal continuous random variable.

As an instance of the `rv_continuous` class, `powerlognorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `powerlognorm` is:

$$f(x, c, s) = \frac{c}{xs} \phi(\log(x)/s) (\Phi(-\log(x)/s))^{c-1}$$

where  $\phi$  is the normal pdf, and  $\Phi$  is the normal cdf, and  $x > 0$ ,  $s, c > 0$ .

`powerlognorm` takes  $c$  and  $s$  as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `powerlognorm.pdf(x, c, s, loc, scale)` is identically equivalent to `powerlognorm.pdf(y, c, s) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import powerlognorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c, s = 2.14, 0.446
>>> mean, var, skew, kurt = powerlognorm.stats(c, s, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(powerlognorm.ppf(0.01, c, s),
... powerlognorm.ppf(0.99, c, s), 100)
>>> ax.plot(x, powerlognorm.pdf(x, c, s),
... 'r-', lw=5, alpha=0.6, label='powerlognorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = powerlognorm(c, s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = powerlognorm.ppf([0.001, 0.5, 0.999], c, s)
>>> np.allclose([0.001, 0.5, 0.999], powerlognorm.cdf(vals, c, s))
True
```

Generate random numbers:

```
>>> r = powerlognorm.rvs(c, s, size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

## Methods

<code>rvs(c, s, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, s, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, s, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, s, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, s, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, s, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, s, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, s, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, c, s, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code> ).
<code>moment(n, c, s, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, s, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, s, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, s, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c, s), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, s, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, s, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, s, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, s, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, s, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.powernorm

`scipy.stats.powernorm` = <`scipy.stats._continuous_distns.powernorm_gen` object>  
 A power normal continuous random variable.

As an instance of the `rv_continuous` class, `powernorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `powernorm` is:

$$f(x, c) = c\phi(x)(\Phi(-x))^{c-1}$$

where  $\phi$  is the normal pdf, and  $\Phi$  is the normal cdf, and  $x \geq 0, c > 0$ .

`powernorm` takes `c` as a shape parameter for  $c$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `powernorm.pdf(x, c, loc, scale)` is identically equivalent to `powernorm.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import powernorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 4.45
>>> mean, var, skew, kurt = powernorm.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(powernorm.ppf(0.01, c),
... powernorm.ppf(0.99, c), 100)
>>> ax.plot(x, powernorm.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='powernorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = powernorm(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = powernorm.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], powernorm.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = powernorm.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.rdist

`scipy.stats.rdist = <scipy.stats._continuous_distns.rdist_gen object>`

An R-distributed continuous random variable.

As an instance of the `rv_continuous` class, `rdist` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `rdist` is:

$$f(x, c) = \frac{(1 - x^2)^{c/2 - 1}}{B(1/2, c/2)}$$

for  $-1 \leq x \leq 1, c > 0$ .

`rdist` takes `c` as a shape parameter for  $c$ .

This distribution includes the following distribution kernels as special cases:

```
c = 2: uniform
c = 4: Epanechnikov (parabolic)
c = 6: quartic (biweight)
c = 8: triweight
```

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `rdist.pdf(x, c, loc, scale)` is identically equivalent to `rdist.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import rdist
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.9
>>> mean, var, skew, kurt = rdist.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(rdist.ppf(0.01, c),
... rdist.ppf(0.99, c), 100)
>>> ax.plot(x, rdist.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='rdist pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = rdist(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = rdist.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], rdist.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = rdist.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.reciprocal

`scipy.stats.reciprocal` = <scipy.stats.\_continuous\_distns.reciprocal\_gen object>  
 A reciprocal continuous random variable.

As an instance of the `rv_continuous` class, `reciprocal` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `reciprocal` is:

$$f(x, a, b) = \frac{1}{x \log(b/a)}$$

for  $a \leq x \leq b, b > a > 0$ .

`reciprocal` takes `a` and `b` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `reciprocal.pdf(x, a, b, loc, scale)` is identically equivalent to `reciprocal.pdf(y, a, b) / scale` with `y = (x - loc) / scale`.

## Examples

```
>>> from scipy.stats import reciprocal
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 0.00623, 1.01
>>> mean, var, skew, kurt = reciprocal.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(reciprocal.ppf(0.01, a, b),
... reciprocal.ppf(0.99, a, b), 100)
>>> ax.plot(x, reciprocal.pdf(x, a, b),
... 'r-', lw=5, alpha=0.6, label='reciprocal pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = reciprocal(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = reciprocal.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], reciprocal.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = reciprocal.rvs(a, b, size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

## Methods

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, b, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.

<code>mean(a, b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.rayleigh

`scipy.stats.rayleigh` = <scipy.stats.\_continuous\_distns.rayleigh\_gen object>  
 A Rayleigh continuous random variable.

As an instance of the *rv\_continuous* class, *rayleigh* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for *rayleigh* is:

$$f(x) = x \exp(-x^2/2)$$

for  $x \geq 0$ .

*rayleigh* is a special case of *chi* with `df=2`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `rayleigh.pdf(x, loc, scale)` is identically equivalent to `rayleigh.pdf(y) / scale` with `y = (x - loc) / scale`.

### Examples

```
>>> from scipy.stats import rayleigh
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = rayleigh.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(rayleigh.ppf(0.01),
... rayleigh.ppf(0.99), 100)
>>> ax.plot(x, rayleigh.pdf(x),
... 'r-', lw=5, alpha=0.6, label='rayleigh pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = rayleigh()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = rayleigh.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], rayleigh.cdf(vals))
True
```

Generate random numbers:

```
>>> r = rayleigh.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.rice

`scipy.stats.rice = <scipy.stats._continuous_distns.rice_gen object>`

A Rice continuous random variable.

As an instance of the `rv_continuous` class, `rice` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `rice` is:

$$f(x, b) = x \exp\left(-\frac{x^2 + b^2}{2}\right) I_0(xb)$$

for  $x \geq 0, b > 0$ .  $I_0$  is the modified Bessel function of order zero (`scipy.special.i0`).

`rice` takes `b` as a shape parameter for  $b$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `rice.pdf(x, b, loc, scale)` is identically equivalent to `rice.pdf(y, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

The Rice distribution describes the length,  $r$ , of a 2-D vector with components  $(U + u, V + v)$ , where  $U, V$  are constant,  $u, v$  are independent Gaussian random variables with standard deviation  $s$ . Let  $R = \sqrt{U^2 + V^2}$ . Then the pdf of  $r$  is `rice.pdf(x, R/s, scale=s)`.

## Examples

```
>>> from scipy.stats import rice
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> b = 0.775
>>> mean, var, skew, kurt = rice.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(rice.ppf(0.01, b),
... rice.ppf(0.99, b), 100)
>>> ax.plot(x, rice.pdf(x, b),
... 'r-', lw=5, alpha=0.6, label='rice pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = rice(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = rice.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], rice.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = rice.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, b, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(b,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## `scipy.stats.recipinvgauss`

`scipy.stats.recipinvgauss` = `<scipy.stats._continuous_distns.recipinvgauss_gen object>`  
 A reciprocal inverse Gaussian continuous random variable.

As an instance of the `rv_continuous` class, `recipinvgauss` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `recipinvgauss` is:

$$f(x, \mu) = \frac{1}{\sqrt{2\pi x}} \exp\left(\frac{-(1 - \mu x)^2}{2\mu^2 x}\right)$$

for  $x \geq 0$ .

`recipinvgauss` takes `mu` as a shape parameter for  $\mu$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `recipinvgauss.pdf(x, mu, loc, scale)` is identically equivalent to `recipinvgauss.pdf(y, mu) / scale` with  $y = (x - loc) / scale$ .

## Examples

```
>>> from scipy.stats import recipinvgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mu = 0.63
>>> mean, var, skew, kurt = recipinvgauss.stats(mu, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(recipinvgauss.ppf(0.01, mu),
... recipinvgauss.ppf(0.99, mu), 100)
>>> ax.plot(x, recipinvgauss.pdf(x, mu),
... 'r-', lw=5, alpha=0.6, label='recipinvgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = recipinvgauss(mu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = recipinvgauss.ppf([0.001, 0.5, 0.999], mu)
>>> np.allclose([0.001, 0.5, 0.999], recipinvgauss.cdf(vals, mu))
True
```

Generate random numbers:

```
>>> r = recipinvgauss.rvs(mu, size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

## Methods

<code>rvs(mu, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, mu, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, mu, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, mu, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, mu, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, mu, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, mu, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, mu, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, mu, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, mu, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(mu, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(mu, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, mu, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(mu,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(mu, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(mu, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(mu, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(mu, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, mu, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.semicircular

`scipy.stats.semicircular` = <`scipy.stats._continuous_distns.semicircular_gen` object>  
 A semicircular continuous random variable.

As an instance of the `rv_continuous` class, `semicircular` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The probability density function for `semicircular` is:

$$f(x) = \frac{2}{\pi} \sqrt{1 - x^2}$$

for  $-1 \leq x \leq 1$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `semicircular.pdf(x, loc, scale)` is identically equivalent to `semicircular.pdf(y) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import semicircular
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = semicircular.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(semicircular.ppf(0.01),
... semicircular.ppf(0.99), 100)
>>> ax.plot(x, semicircular.pdf(x),
... 'r-', lw=5, alpha=0.6, label='semicircular pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = semicircular()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = semicircular.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], semicircular.cdf(vals))
True
```

Generate random numbers:

```
>>> r = semicircular.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.skewnorm

`scipy.stats.skewnorm` = <`scipy.stats._continuous_distns.skew_norm_gen` object>  
A skew-normal random variable.

As an instance of the `rv_continuous` class, `skewnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The pdf is:

$$\text{skewnorm.pdf}(x, a) = 2 * \text{norm.pdf}(x) * \text{norm.cdf}(a*x)$$

`skewnorm` takes a real number *a* as a skewness parameter. When *a* = 0 the distribution is identical to a normal distribution (`norm`). `rvs` implements the method of [1].

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `skewnorm.pdf(x, a, loc, scale)` is identically equivalent to `skewnorm.pdf(y, a) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## References

[1]

## Examples

```
>>> from scipy.stats import skewnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 4
>>> mean, var, skew, kurt = skewnorm.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(skewnorm.ppf(0.01, a),
... skewnorm.ppf(0.99, a), 100)
>>> ax.plot(x, skewnorm.pdf(x, a),
... 'r-', lw=5, alpha=0.6, label='skewnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = skewnorm(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = skewnorm.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], skewnorm.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = skewnorm.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

## scipy.stats.t

`scipy.stats.t` = <scipy.stats.\_continuous\_distns.t\_gen object>  
 A Student's t continuous random variable.

As an instance of the `rv_continuous` class, `t` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `t` is:

$$f(x, \nu) = \frac{\Gamma((\nu + 1)/2)}{\sqrt{\pi\nu}\Gamma(\nu)} (1 + x^2/\nu)^{-(\nu+1)/2}$$

where  $x$  is a real number and the degrees of freedom parameter  $\nu$  (denoted `df` in the implementation) satisfies  $\nu > 0$ .  $\Gamma$  is the gamma function (`scipy.special.gamma`).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `t.pdf(x, df, loc, scale)` is identically equivalent to `t.pdf(y, df) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import t
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> df = 2.74
>>> mean, var, skew, kurt = t.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(t.ppf(0.01, df),
... t.ppf(0.99, df), 100)
>>> ax.plot(x, t.pdf(x, df),
... 'r-', lw=5, alpha=0.6, label='t pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = t(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = t.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], t.cdf(vals, df))
True
```

Generate random numbers:

```
>>> r = t.rvs(df, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(df, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, df, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, df, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, df, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, df, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, df, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, df, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, df, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, df, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, df, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(df, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(df, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, df, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(df,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(df, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(df, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(df, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(df, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, df, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.trapz

`scipy.stats.trapz` = <scipy.stats.\_continuous\_distns.trapz\_gen object>

A trapezoidal continuous random variable.

As an instance of the *rv\_continuous* class, *trapz* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The trapezoidal distribution can be represented with an up-sloping line from *loc* to (*loc* + *c*\**scale*), then constant to (*loc* + *d*\**scale*) and then downsloping from (*loc* + *d*\**scale*) to (*loc*+*scale*).

*trapz* takes *c* and *d* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `trapz.pdf(x, c, d, loc, scale)` is identically equivalent to `trapz.pdf(y, c, d) / scale` with  $y = (x - loc) / scale$ .

The standard form is in the range [0, 1] with *c* the mode. The location parameter shifts the start to *loc*. The scale parameter changes the width from 1 to *scale*.

### Examples

```
>>> from scipy.stats import trapz
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c, d = 0.2, 0.8
>>> mean, var, skew, kurt = trapz.stats(c, d, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(trapz.ppf(0.01, c, d),
... trapz.ppf(0.99, c, d), 100)
>>> ax.plot(x, trapz.pdf(x, c, d),
... 'r-', lw=5, alpha=0.6, label='trapz pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = trapz(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = trapz.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], trapz.cdf(vals, c, d))
True
```

Generate random numbers:

```
>>> r = trapz.rvs(c, d, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, d, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, d, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, d, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, d, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, d, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, d, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, d, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, d, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, d, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, d, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, d, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, d, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, d, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c, d), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, d, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, d, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, d, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, d, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, d, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.triang

`scipy.stats.triang = <scipy.stats._continuous_distns.triang_gen object>`

A triangular continuous random variable.

As an instance of the `rv_continuous` class, `triang` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The triangular distribution can be represented with an up-sloping line from `loc` to `(loc + c*scale)` and then downsloping for `(loc + c*scale)` to `(loc + scale)`.

`triang` takes `c` as a shape parameter for `c`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `triang.pdf(x, c, loc, scale)` is identically equivalent to `triang.pdf(y, c) / scale` with `y = (x - loc) / scale`.

The standard form is in the range `[0, 1]` with `c` the mode. The location parameter shifts the start to `loc`. The scale parameter changes the width from 1 to `scale`.

## Examples

```
>>> from scipy.stats import triang
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.158
>>> mean, var, skew, kurt = triang.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(triang.ppf(0.01, c),
... triang.ppf(0.99, c), 100)
>>> ax.plot(x, triang.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='triang pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = triang(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = triang.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], triang.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = triang.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but $\text{sf}$ is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of $\text{cdf}$ — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of $\text{sf}$ ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order $n$
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.truncexpon

`scipy.stats.truncexpon` = <scipy.stats.\_continuous\_distns.truncexpon\_gen object>  
 A truncated exponential continuous random variable.

As an instance of the *rv\_continuous* class, *truncexpon* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for *truncexpon* is:

$$f(x, b) = \frac{\exp(-x)}{1 - \exp(-b)}$$

for  $0 \leq x \leq b$ .

*truncexpon* takes *b* as a shape parameter for *b*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `truncexpon.pdf(x, b, loc, scale)` is identically equivalent to `truncexpon.pdf(y, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import truncexpon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> b = 4.69
>>> mean, var, skew, kurt = truncexpon.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(truncexpon.ppf(0.01, b),
... truncexpon.ppf(0.99, b), 100)
>>> ax.plot(x, truncexpon.pdf(x, b),
... 'r-', lw=5, alpha=0.6, label='truncexpon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = truncexpon(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = truncexpon.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], truncexpon.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = truncexpon.rvs(b, size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

## Methods

<code>rvs(b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, b, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(b,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, b, loc=0, scale=1)</code>	Endpoints of the range that contains <i>alpha</i> percent of the distribution

## scipy.stats.truncnorm

`scipy.stats.truncnorm` = <`scipy.stats._continuous_distns.truncnorm_gen` object>  
 A truncated normal continuous random variable.

As an instance of the *rv\_continuous* class, *truncnorm* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### Notes

The standard form of this distribution is a standard normal truncated to the range  $[a, b]$  — notice that  $a$  and  $b$  are defined over the domain of the standard normal. To convert clip values for a specific mean and standard deviation, use:

```
a, b = (myclip_a - my_mean) / my_std, (myclip_b - my_mean) / my_std
```

*truncnorm* takes  $a$  and  $b$  as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `truncnorm.pdf(x, a, b, loc, scale)` is identically equivalent to `truncnorm.pdf(y, a, b) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import truncnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a, b = 0.1, 2
>>> mean, var, skew, kurt = truncnorm.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(truncnorm.ppf(0.01, a, b),
... truncnorm.ppf(0.99, a, b), 100)
>>> ax.plot(x, truncnorm.pdf(x, a, b),
... 'r-', lw=5, alpha=0.6, label='truncnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = truncnorm(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = truncnorm.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], truncnorm.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = truncnorm.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, a, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, a, b, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.tukeylambda

`scipy.stats.tukeylambda` = <scipy.stats.\_continuous\_distns.tukeylambda\_gen object>

A Tukey-Lambda continuous random variable.

As an instance of the `rv_continuous` class, `tukeylambda` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

A flexible distribution, able to represent and interpolate between the following distributions:

- Cauchy ( $\lambda = -1$ )
- logistic ( $\lambda = 0$ )
- approx Normal ( $\lambda = 0.14$ )
- uniform from -1 to 1 ( $\lambda = 1$ )

`tukeylambda` takes a real number  $\lambda$  (denoted `lam` in the implementation) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `tukeylambda.pdf(x, lam, loc, scale)` is identically equivalent to `tukeylambda.pdf(y, lam) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import tukeylambd
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> lam = 3.13
>>> mean, var, skew, kurt = tukeylambd.stats(lam, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(tukeylambd.ppf(0.01, lam),
... tukeylambd.ppf(0.99, lam), 100)
>>> ax.plot(x, tukeylambd.pdf(x, lam),
... 'r-', lw=5, alpha=0.6, label='tukeylambd pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = tukeylambd(lam)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = tukeylambd.ppf([0.001, 0.5, 0.999], lam)
>>> np.allclose([0.001, 0.5, 0.999], tukeylambd.cdf(vals, lam))
True
```

Generate random numbers:

```
>>> r = tukeylambd.rvs(lam, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(lam, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, lam, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, lam, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, lam, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, lam, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, lam, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, lam, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, lam, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, lam, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, lam, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(lam, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(lam, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, lam, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(lam,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(lam, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(lam, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(lam, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(lam, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, lam, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.uniform

`scipy.stats.uniform` = <`scipy.stats._continuous_distns.uniform_gen` object>  
 A uniform continuous random variable.

In the standard form, the distribution is uniform on  $[0, 1]$ . Using the parameters `loc` and `scale`, one obtains the uniform distribution on  $[\text{loc}, \text{loc} + \text{scale}]$ .

As an instance of the `rv_continuous` class, `uniform` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Examples

```
>>> from scipy.stats import uniform
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = uniform.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(uniform.ppf(0.01),
... uniform.ppf(0.99), 100)
>>> ax.plot(x, uniform.pdf(x),
... 'r-', lw=5, alpha=0.6, label='uniform pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = uniform()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = uniform.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], uniform.cdf(vals))
True
```

Generate random numbers:

```
>>> r = uniform.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.vonmises

`scipy.stats.vonmises` = <`scipy.stats._continuous_distns.vonmises_gen` object>  
 A Von Mises continuous random variable.

As an instance of the `rv_continuous` class, `vonmises` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `vonmises` and `vonmises_line` is:

$$f(x, \kappa) = \frac{\exp(\kappa \cos(x))}{2\pi I_0(\kappa)}$$

for  $-\pi \leq x \leq \pi$ ,  $\kappa > 0$ .  $I_0$  is the modified Bessel function of order zero (`scipy.special.i0`).

`vonmises` is a circular distribution which does not restrict the distribution to a fixed interval. Currently, there is no circular distribution framework in `scipy`. The `cdf` is implemented such that `cdf(x + 2*np.pi) == cdf(x) + 1`.

`vonmises_line` is the same distribution, defined on  $[-\pi, \pi]$  on the real line. This is a regular (i.e. non-circular) distribution.

`vonmises` and `vonmises_line` take `kappa` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `vonmises.pdf(x, kappa, loc, scale)` is identically equivalent to `vonmises.pdf(y, kappa) / scale` with `y = (x - loc) / scale`.

## Examples

```
>>> from scipy.stats import vonmises
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> kappa = 3.99
>>> mean, var, skew, kurt = vonmises.stats(kappa, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(vonmises.ppf(0.01, kappa),
... vonmises.ppf(0.99, kappa), 100)
>>> ax.plot(x, vonmises.pdf(x, kappa),
... 'r-', lw=5, alpha=0.6, label='vonmises pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = vonmises(kappa)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of `cdf` and `ppf`:

```
>>> vals = vonmises.ppf([0.001, 0.5, 0.999], kappa)
>>> np.allclose([0.001, 0.5, 0.999], vonmises.cdf(vals, kappa))
True
```

Generate random numbers:

```
>>> r = vonmises.rvs(kappa, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(kappa, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, kappa, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, kappa, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, kappa, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, kappa, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, kappa, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, kappa, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, kappa, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, kappa, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, kappa, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(kappa, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(kappa, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, kappa, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(kappa,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(kappa, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(kappa, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(kappa, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(kappa, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, kappa, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.vonmises\_line

`scipy.stats.vonmises_line = <scipy.stats._continuous_distns.vonmises_gen object>`  
 A Von Mises continuous random variable.

As an instance of the `rv_continuous` class, `vonmises_line` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `vonmises` and `vonmises_line` is:

$$f(x, \kappa) = \frac{\exp(\kappa \cos(x))}{2\pi I_0(\kappa)}$$

for  $-\pi \leq x \leq \pi$ ,  $\kappa > 0$ .  $I_0$  is the modified Bessel function of order zero (`scipy.special.i0`).

`vonmises` is a circular distribution which does not restrict the distribution to a fixed interval. Currently, there is no circular distribution framework in `scipy`. The *cdf* is implemented such that `cdf(x + 2*np.pi) == cdf(x) + 1`.

`vonmises_line` is the same distribution, defined on  $[-\pi, \pi]$  on the real line. This is a regular (i.e. non-circular) distribution.

`vonmises` and `vonmises_line` take `kappa` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `vonmises_line.pdf(x, kappa, loc, scale)` is identically equivalent to `vonmises_line.pdf(y, kappa) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import vonmises_line
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> kappa = 3.99
>>> mean, var, skew, kurt = vonmises_line.stats(kappa, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(vonmises_line.ppf(0.01, kappa),
... vonmises_line.ppf(0.99, kappa), 100)
>>> ax.plot(x, vonmises_line.pdf(x, kappa),
... 'r-', lw=5, alpha=0.6, label='vonmises_line pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = vonmises_line(kappa)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = vonmises_line.ppf([0.001, 0.5, 0.999], kappa)
>>> np.allclose([0.001, 0.5, 0.999], vonmises_line.cdf(vals, kappa))
True
```

Generate random numbers:

```
>>> r = vonmises_line.rvs(kappa, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(kappa, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, kappa, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, kappa, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, kappa, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, kappa, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, kappa, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, kappa, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, kappa, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, kappa, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, kappa, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(kappa, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(kappa, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, kappa, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(kappa,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(kappa, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(kappa, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(kappa, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(kappa, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, kappa, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.wald

`scipy.stats.wald = <scipy.stats._continuous_distns.wald_gen object>`  
 A Wald continuous random variable.

As an instance of the `rv_continuous` class, `wald` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `wald` is:

$$f(x) = \frac{1}{\sqrt{2\pi x^3}} \exp\left(-\frac{(x-1)^2}{2x}\right)$$

for  $x \geq 0$ .

`wald` is a special case of `invgauss` with `mu=1`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `wald.pdf(x, loc, scale)` is identically equivalent to `wald.pdf(y) / scale` with `y = (x - loc) / scale`.

## Examples

```
>>> from scipy.stats import wald
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mean, var, skew, kurt = wald.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(wald.ppf(0.01),
... wald.ppf(0.99), 100)
>>> ax.plot(x, wald.pdf(x),
... 'r-', lw=5, alpha=0.6, label='wald pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = wald()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = wald.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], wald.cdf(vals))
True
```

Generate random numbers:

```
>>> r = wald.rvs(size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

## Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.weibull\_min

`scipy.stats.weibull_min` = <`scipy.stats._continuous_distns.weibull_min_gen` object>  
Weibull minimum continuous random variable.

As an instance of the `rv_continuous` class, `weibull_min` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

### See also:

`weibull_max`

### Notes

The probability density function for `weibull_min` is:

$$f(x, c) = cx^{c-1} \exp(-x^c)$$

for  $x \geq 0, c > 0$ .

`weibull_min` takes `c` as a shape parameter for  $c$ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `weibull_min.pdf(x, c, loc, scale)` is identically equivalent to `weibull_min.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

### Examples

```
>>> from scipy.stats import weibull_min
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 1.79
>>> mean, var, skew, kurt = weibull_min.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(weibull_min.ppf(0.01, c),
... weibull_min.ppf(0.99, c), 100)
>>> ax.plot(x, weibull_min.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='weibull_min pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = weibull_min(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = weibull_min.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], weibull_min.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = weibull_min.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

### scipy.stats.weibull\_max

`scipy.stats.weibull_max` = <scipy.stats.\_continuous\_distns.weibull\_max\_gen object>  
Weibull maximum continuous random variable.

As an instance of the *rv\_continuous* class, *weibull\_max* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

*weibull\_min*

### Notes

The probability density function for *weibull\_max* is:

$$f(x, c) = c(-x)^{c-1} \exp(-(-x)^c)$$

for  $x < 0, c > 0$ .

*weibull\_max* takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `weibull_max.pdf(x, c, loc, scale)` is identically equivalent to `weibull_max.pdf(y, c) / scale` with  $y = (x - \text{loc}) / \text{scale}$ .

## Examples

```
>>> from scipy.stats import weibull_max
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 2.87
>>> mean, var, skew, kurt = weibull_max.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(weibull_max.ppf(0.01, c),
... weibull_max.ppf(0.99, c), 100)
>>> ax.plot(x, weibull_max.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='weibull_max pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = weibull_max(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = weibull_max.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], weibull_max.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = weibull_max.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but $\text{sf}$ is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of $\text{cdf}$ — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of $\text{sf}$ ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order $n$
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.wrapcauchy

`scipy.stats.wrapcauchy` = `<scipy.stats._continuous_distns.wrapcauchy_gen object>`  
 A wrapped Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `wrapcauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability density function for `wrapcauchy` is:

$$f(x, c) = \frac{1 - c^2}{2\pi(1 + c^2 - 2c \cos(x))}$$

for  $0 \leq x \leq 2\pi$ ,  $0 < c < 1$ .

`wrapcauchy` takes `c` as a shape parameter for `c`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `wrapcauchy.pdf(x, c, loc, scale)` is identically equivalent to `wrapcauchy.pdf(y, c) / scale` with `y = (x - loc) / scale`.

## Examples

```
>>> from scipy.stats import wrapcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> c = 0.0311
>>> mean, var, skew, kurt = wrapcauchy.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(wrapcauchy.ppf(0.01, c),
... wrapcauchy.ppf(0.99, c), 100)
>>> ax.plot(x, wrapcauchy.pdf(x, c),
... 'r-', lw=5, alpha=0.6, label='wrapcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = wrapcauchy(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = wrapcauchy.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], wrapcauchy.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = wrapcauchy.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

## Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data, c, loc=0, scale=1)</code>	Parameter estimates for generic data.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains <i>alpha</i> percent of the distribution

## 6.28.5 Multivariate distributions

<code>multivariate_normal</code>	A multivariate normal random variable.
<code>matrix_normal</code>	A matrix normal random variable.
<code>dirichlet</code>	A Dirichlet random variable.
<code>wishart</code>	A Wishart random variable.
<code>invwishart</code>	An inverse Wishart random variable.
<code>multinomial</code>	A multinomial random variable.
<code>special_ortho_group</code>	A matrix-valued SO(N) random variable.
<code>ortho_group</code>	A matrix-valued O(N) random variable.
<code>unitary_group</code>	A matrix-valued U(N) random variable.
<code>random_correlation</code>	A random correlation matrix.

### scipy.stats.multivariate\_normal

`scipy.stats.multivariate_normal` = <`scipy.stats._multivariate.multivariate_normal_gen` object

A multivariate normal random variable.

The *mean* keyword specifies the mean. The *cov* keyword specifies the covariance matrix.

#### Parameters

- x** [array\_like] Quantiles, with the last axis of *x* denoting the components.
- mean** [array\_like, optional] Mean of the distribution (default zero)
- cov** [array\_like, optional] Covariance matrix of the distribution (default one)
- allow\_singular** [bool, optional] Whether to allow a singular covariance matrix. (Default: False)
- random\_state** [None or int or np.random.RandomState instance, optional] If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

Alternatively, the object may be called (as a function) to fix the mean and covariance parameters, returning a “frozen” multivariate normal random variable:

```
rv = multivariate_normal(mean=None, cov=1, allow_singular=False)
```

- Frozen object with the same methods but holding the given mean and covariance fixed.

#### Notes

##### Setting the parameter mean to None is equivalent to having mean

be the zero-vector. The parameter *cov* can be a scalar, in which case the covariance matrix is the identity times that value, a vector of diagonal entries for the covariance matrix, or a two-dimensional array\_like.

The covariance matrix *cov* must be a (symmetric) positive semi-definite matrix. The determinant and inverse of *cov* are computed as the pseudo-determinant and pseudo-inverse, respectively, so that *cov* does not need to have full rank.

The probability density function for `multivariate_normal` is

$$f(x) = \frac{1}{\sqrt{(2\pi)^k \det \Sigma}} \exp\left(-\frac{1}{2}(x - \mu)^T \Sigma^{-1} (x - \mu)\right),$$

where  $\mu$  is the mean,  $\Sigma$  the covariance matrix, and  $k$  is the dimension of the space where  $x$  takes values.

New in version 0.14.0.

## Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import multivariate_normal
```

```
>>> x = np.linspace(0, 5, 10, endpoint=False)
>>> y = multivariate_normal.pdf(x, mean=2.5, cov=0.5); y
array([0.00108914, 0.01033349, 0.05946514, 0.20755375, 0.43939129,
 0.56418958, 0.43939129, 0.20755375, 0.05946514, 0.01033349])
>>> fig1 = plt.figure()
>>> ax = fig1.add_subplot(111)
>>> ax.plot(x, y)
```

The input quantiles can be any shape of array, as long as the last axis labels the components. This allows us for instance to display the frozen pdf for a non-isotropic random variable in 2D as follows:

```
>>> x, y = np.mgrid[-1:1:.01, -1:1:.01]
>>> pos = np.dstack((x, y))
>>> rv = multivariate_normal([0.5, -0.2], [[2.0, 0.3], [0.3, 0.5]])
>>> fig2 = plt.figure()
>>> ax2 = fig2.add_subplot(111)
>>> ax2.contourf(x, y, rv.pdf(pos))
```

## Methods

<code>“pdf(x, mean=None, cov=1, allow_singular=False)”</code>	Probability density function.
<code>“logpdf(x, mean=None, cov=1, allow_singular=False)”</code>	Log of the probability density function.
<code>“cdf(x, mean=None, cov=1, allow_singular=False, maxpts=100000*dim, abseps=1e-5, releps=1e-5)”</code>	Cumulative distribution function.
<code>“logcdf(x, mean=None, cov=1, allow_singular=False, maxpts=100000*dim, abseps=1e-5, releps=1e-5)”</code>	Log of the cumulative distribution function.
<code>“rvs(mean=None, cov=1, size=1, random_state=None)”</code>	Draw random samples from a multivariate normal distribution.
<code>“entropy()”</code>	Compute the differential entropy of the multivariate normal.

## scipy.stats.matrix\_normal

`scipy.stats.matrix_normal = <scipy.stats._multivariate.matrix_normal_gen object>`  
 A matrix normal random variable.

The *mean* keyword specifies the mean. The *rowcov* keyword specifies the among-row covariance matrix. The ‘*colcov*’ keyword specifies the among-column covariance matrix.

### Parameters

**X** [array\_like] Quantiles, with the last two axes of *X* denoting the components.  
**mean** [array\_like, optional] Mean of the distribution (default: *None*)  
**rowcov** [array\_like, optional] Among-row covariance matrix of the distribution (default: *I*)  
**colcov** [array\_like, optional] Among-column covariance matrix of the distribution (default: *I*)  
**random\_state** [None or int or np.random.RandomState instance, optional] If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

Alternatively, the object may be called (as a function) to fix the mean and covariance parameters, returning a “frozen” matrix normal

**random variable:**

`rv = matrix_normal(mean=None, rowcov=1, colcov=1)`

- Frozen object with the same methods but holding the given mean and covariance fixed.

## Notes

*If mean is set to None then a matrix of zeros is used for the mean.*

The dimensions of this matrix are inferred from the shape of `rowcov` and `colcov`, if these are provided, or set to 1 if ambiguous.

`rowcov` and `colcov` can be two-dimensional array\_likes specifying the covariance matrices directly. Alternatively, a one-dimensional array will be interpreted as the entries of a diagonal matrix, and a scalar or zero-dimensional array will be interpreted as this value times the identity matrix.

The covariance matrices specified by `rowcov` and `colcov` must be (symmetric) positive definite. If the samples in  $X$  are  $m \times n$ , then `rowcov` must be  $m \times m$  and `colcov` must be  $n \times n$ . `mean` must be the same shape as  $X$ .

The probability density function for `matrix_normal` is

$$f(X) = (2\pi)^{-\frac{mn}{2}} |U|^{-\frac{n}{2}} |V|^{-\frac{m}{2}} \exp\left(-\frac{1}{2} \text{Tr}[U^{-1}(X - M)V^{-1}(X - M)^T]\right),$$

where  $M$  is the mean,  $U$  the among-row covariance matrix,  $V$  the among-column covariance matrix.

The `allow_singular` behaviour of the `multivariate_normal` distribution is not currently supported. Covariance matrices must be full rank.

The `matrix_normal` distribution is closely related to the `multivariate_normal` distribution. Specifically,  $\text{Vec}(X)$  (the vector formed by concatenating the columns of  $X$ ) has a multivariate normal distribution with mean  $\text{Vec}(M)$  and covariance  $V \otimes U$  (where  $\otimes$  is the Kronecker product). Sampling and pdf evaluation are  $\mathcal{O}(m^3 + n^3 + m^2n + mn^2)$  for the matrix normal, but  $\mathcal{O}(m^3n^3)$  for the equivalent multivariate normal, making this equivalent form algorithmically inefficient.

New in version 0.17.0.

## Examples

```
>>> from scipy.stats import matrix_normal
```

```
>>> M = np.arange(6).reshape(3,2); M
array([[0, 1],
 [2, 3],
 [4, 5]])
>>> U = np.diag([1,2,3]); U
array([[1, 0, 0],
 [0, 2, 0],
 [0, 0, 3]])
>>> V = 0.3*np.identity(2); V
array([[0.3, 0.],
 [0. , 0.3]])
>>> X = M + 0.1; X
array([[0.1, 1.1],
 [2.1, 3.1],
```

(continues on next page)

(continued from previous page)

```
[4.1, 5.1]])
>>> matrix_normal.pdf(X, mean=M, rowcov=U, colcov=V)
0.023410202050005054
```

```
>>> # Equivalent multivariate normal
>>> from scipy.stats import multivariate_normal
>>> vectorised_X = X.T.flatten()
>>> equiv_mean = M.T.flatten()
>>> equiv_cov = np.kron(V,U)
>>> multivariate_normal.pdf(vectorised_X, mean=equiv_mean, cov=equiv_cov)
0.023410202050005054
```

### Methods

“pdf(X, mean=None, rowcov=1, colcov=1)“	Probability density function.
“logpdf(X, mean=None, rowcov=1, colcov=1)“	Log of the probability density function.
“rvs(mean=None, rowcov=1, colcov=1, size=1, random_state=None)“	Draw random samples.

### scipy.stats.dirichlet

scipy.stats.dirichlet = <scipy.stats.\_multivariate.dirichlet\_gen object>  
 A Dirichlet random variable.

The *alpha* keyword specifies the concentration parameters of the distribution.

New in version 0.15.0.

#### Parameters

- x** [array\_like] Quantiles, with the last axis of *x* denoting the components.
- alpha** [array\_like] The concentration parameters. The number of entries determines the dimensionality of the distribution.
- random\_state** [None or int or np.random.RandomState instance, optional] If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

Alternatively, the object may be called (as a function) to fix concentration parameters, returning a “frozen” Dirichlet random variable:

**rv = dirichlet(alpha)**

- Frozen object with the same methods but holding the given concentration parameters fixed.

### Notes

Each  $\alpha$  entry must be positive. The distribution has only support on the simplex defined by

$$\sum_{i=1}^K x_i \leq 1$$

The probability density function for *dirichlet* is

$$f(x) = \frac{1}{B(\alpha)} \prod_{i=1}^K x_i^{\alpha_i - 1}$$

where

$$B(\alpha) = \frac{\prod_{i=1}^K \Gamma(\alpha_i)}{\Gamma(\sum_{i=1}^K \alpha_i)}$$

and  $\alpha = (\alpha_1, \dots, \alpha_K)$ , the concentration parameters and  $K$  is the dimension of the space where  $x$  takes values.

Note that the *dirichlet* interface is somewhat inconsistent. The array returned by the *rvs* function is transposed with respect to the format expected by the *pdf* and *logpdf*.

## Examples

```
>>> from scipy.stats import dirichlet
```

Generate a *dirichlet* random variable

```
>>> quantiles = np.array([0.2, 0.2, 0.6]) # specify quantiles
>>> alpha = np.array([0.4, 5, 15]) # specify concentration parameters
>>> dirichlet.pdf(quantiles, alpha)
0.2843831684937255
```

The same PDF but following a log scale

```
>>> dirichlet.logpdf(quantiles, alpha)
-1.2574327653159187
```

Once we specify the *dirichlet* distribution we can then calculate quantities of interest

```
>>> dirichlet.mean(alpha) # get the mean of the distribution
array([0.01960784, 0.24509804, 0.73529412])
>>> dirichlet.var(alpha) # get variance
array([0.00089829, 0.00864603, 0.00909517])
>>> dirichlet.entropy(alpha) # calculate the differential entropy
-4.3280162474082715
```

We can also return random samples from the distribution

```
>>> dirichlet.rvs(alpha, size=1, random_state=1)
array([[0.00766178, 0.24670518, 0.74563305]])
>>> dirichlet.rvs(alpha, size=2, random_state=2)
array([[0.01639427, 0.1292273 , 0.85437844],
 [0.00156917, 0.19033695, 0.80809388]])
```

## Methods

<code>“pdf(x, alpha)“</code>	Probability density function.
<code>“logpdf(x, alpha)“</code>	Log of the probability density function.
<code>“rvs(alpha, size=1, random_state=None)“</code>	Draw random samples from a Dirichlet distribution.
<code>“mean(alpha)“</code>	The mean of the Dirichlet distribution
<code>“var(alpha)“</code>	The variance of the Dirichlet distribution
<code>“entropy(alpha)“</code>	Compute the differential entropy of the Dirichlet distribution.

## scipy.stats.wishart

`scipy.stats.wishart = <scipy.stats._multivariate.wishart_gen object>`

A Wishart random variable.

The *df* keyword specifies the degrees of freedom. The *scale* keyword specifies the scale matrix, which must be symmetric and positive definite. In this context, the scale matrix is often interpreted in terms of a multivariate normal precision matrix (the inverse of the covariance matrix).

### Parameters

**x** [array\_like] Quantiles, with the last axis of *x* denoting the components.  
**df** [int] Degrees of freedom, must be greater than or equal to dimension of the scale matrix  
**scale** [array\_like] Symmetric positive definite scale matrix of the distribution  
**random\_state** [None or int or np.random.RandomState instance, optional] If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

Alternatively, the object may be called (as a function) to fix the degrees of freedom and scale parameters, returning a “frozen” Wishart random variable:

```
rv = wishart(df=1, scale=1)
```

- Frozen object with the same methods but holding the given degrees of freedom and scale fixed.

See also:

`invwishart`, `chi2`

## Notes

The scale matrix *scale* must be a symmetric positive definite matrix. Singular matrices, including the symmetric positive semi-definite case, are not supported.

The Wishart distribution is often denoted

$$W_p(\nu, \Sigma)$$

where  $\nu$  is the degrees of freedom and  $\Sigma$  is the  $p \times p$  scale matrix.

The probability density function for `wishart` has support over positive definite matrices  $S$ ; if  $S \sim W_p(\nu, \Sigma)$ , then its PDF is given by:

$$f(S) = \frac{|S|^{\frac{\nu-p-1}{2}}}{2^{\frac{\nu p}{2}} |\Sigma|^{\frac{\nu}{2}} \Gamma_p\left(\frac{\nu}{2}\right)} \exp(-tr(\Sigma^{-1}S)/2)$$

If  $S \sim W_p(\nu, \Sigma)$  (Wishart) then  $S^{-1} \sim W_p^{-1}(\nu, \Sigma^{-1})$  (inverse Wishart).

If the scale matrix is 1-dimensional and equal to one, then the Wishart distribution  $W_1(\nu, 1)$  collapses to the  $\chi^2(\nu)$  distribution.

New in version 0.16.0.

## References

[1], [2]

## Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import wishart, chi2
>>> x = np.linspace(1e-5, 8, 100)
>>> w = wishart.pdf(x, df=3, scale=1); w[:5]
array([0.00126156, 0.10892176, 0.14793434, 0.17400548, 0.1929669])
>>> c = chi2.pdf(x, 3); c[:5]
array([0.00126156, 0.10892176, 0.14793434, 0.17400548, 0.1929669])
>>> plt.plot(x, w)
```

The input quantiles can be any shape of array, as long as the last axis labels the components.

## Methods

“pdf(x, df, scale)”	Probability density function.
“logpdf(x, df, scale)”	Log of the probability density function.
“rvs(df, scale, size=1, random_state=None)”	Draw random samples from a Wishart distribution.
“entropy()”	Compute the differential entropy of the Wishart distribution.

**scipy.stats.invwishart**

`scipy.stats.invwishart` = <`scipy.stats._multivariate.invwishart_gen` object>

An inverse Wishart random variable.

The *df* keyword specifies the degrees of freedom. The *scale* keyword specifies the scale matrix, which must be symmetric and positive definite. In this context, the scale matrix is often interpreted in terms of a multivariate normal covariance matrix.

**Parameters**

- x** [array\_like] Quantiles, with the last axis of *x* denoting the components.
- df** [int] Degrees of freedom, must be greater than or equal to dimension of the scale matrix
- scale** [array\_like] Symmetric positive definite scale matrix of the distribution
- random\_state** [None or int or np.random.RandomState instance, optional] If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

**Alternatively, the object may be called (as a function) to fix the degrees of freedom and scale parameters, returning a “frozen” inverse Wishart random variable:**

**`rv = invwishart(df=1, scale=1)`**

- Frozen object with the same methods but holding the given degrees of freedom and scale fixed.

**See also:**

`wishart`

**Notes**

The scale matrix *scale* must be a symmetric positive definite matrix. Singular matrices, including the symmetric positive semi-definite case, are not supported.

The inverse Wishart distribution is often denoted

$$W_p^{-1}(\nu, \Psi)$$

where  $\nu$  is the degrees of freedom and  $\Psi$  is the  $p \times p$  scale matrix.

The probability density function for `invwishart` has support over positive definite matrices  $S$ ; if  $S \sim W_p^{-1}(\nu, \Sigma)$ , then its PDF is given by:

$$f(S) = \frac{|\Sigma|^{\frac{\nu}{2}}}{2^{\frac{\nu p}{2}} |S|^{\frac{\nu+p+1}{2}} \Gamma_p\left(\frac{\nu}{2}\right)} \exp(-tr(\Sigma S^{-1})/2)$$

If  $S \sim W_p^{-1}(\nu, \Psi)$  (inverse Wishart) then  $S^{-1} \sim W_p(\nu, \Psi^{-1})$  (Wishart).

If the scale matrix is 1-dimensional and equal to one, then the inverse Wishart distribution  $W_1(\nu, 1)$  collapses to the inverse Gamma distribution with parameters shape =  $\frac{\nu}{2}$  and scale =  $\frac{1}{2}$ .

New in version 0.16.0.

**References**

[1], [2]

## Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import invwishart, invgamma
>>> x = np.linspace(0.01, 1, 100)
>>> iw = invwishart.pdf(x, df=6, scale=1)
>>> iw[:3]
array([1.20546865e-15, 5.42497807e-06, 4.45813929e-03])
>>> ig = invgamma.pdf(x, 6/2., scale=1./2)
>>> ig[:3]
array([1.20546865e-15, 5.42497807e-06, 4.45813929e-03])
>>> plt.plot(x, iw)
```

The input quantiles can be any shape of array, as long as the last axis labels the components.

## Methods

“pdf(x, df, scale)“	Probability density function.
“logpdf(x, df, scale)“	Log of the probability density function.
“rvs(df, scale, size=1, random_state=None)“	Draw random samples from an inverse Wishart distribution.

## scipy.stats.multinomial

`scipy.stats.multinomial` = <scipy.stats.\_multivariate.multinomial\_gen object>  
A multinomial random variable.

### Parameters

- x** [array\_like] Quantiles, with the last axis of *x* denoting the components.
- n** [int] Number of trials
- p** [array\_like] Probability of a trial falling into each category; should sum to 1

**random\_state**

[None or int or np.random.RandomState instance, optional] If int or RandomState, use it for drawing the random variates. If None (or np.random), the global np.random state is used. Default is None.

**See also:**

`scipy.stats.binom`

The binomial distribution.

`numpy.random.Generator.multinomial`

Sampling from the multinomial distribution.

**Notes**

$n$  should be a positive integer. Each element of  $p$  should be in the interval  $[0, 1]$  and the elements should sum to 1. If they do not sum to 1, the last element of the  $p$  array is not used and is replaced with the remaining probability left over from the earlier elements.

Alternatively, the object may be called (as a function) to fix the  $n$  and  $p$  parameters, returning a “frozen” multinomial random variable:

The probability mass function for `multinomial` is

$$f(x) = \frac{n!}{x_1! \dots x_k!} p_1^{x_1} \dots p_k^{x_k},$$

supported on  $x = (x_1, \dots, x_k)$  where each  $x_i$  is a nonnegative integer and their sum is  $n$ .

New in version 0.19.0.

**Examples**

```
>>> from scipy.stats import multinomial
>>> rv = multinomial(8, [0.3, 0.2, 0.5])
>>> rv.pmf([1, 3, 4])
0.0420000000000000072
```

The multinomial distribution for  $k = 2$  is identical to the corresponding binomial distribution (tiny numerical differences notwithstanding):

```
>>> from scipy.stats import binom
>>> multinomial.pmf([3, 4], n=7, p=[0.4, 0.6])
0.29030399999999973
>>> binom.pmf(3, 7, 0.4)
0.29030400000000012
```

The functions `pmf`, `logpmf`, `entropy`, and `cov` support broadcasting, under the convention that the vector parameters ( $x$  and  $p$ ) are interpreted as if each row along the last axis is a single object. For instance:

```
>>> multinomial.pmf([[3, 4], [3, 5]], n=[7, 8], p=[.3, .7])
array([0.2268945, 0.25412184])
```

Here, `x.shape == (2, 2)`, `n.shape == (2,)`, and `p.shape == (2,)`, but following the rules mentioned above they behave as if the rows `[3, 4]` and `[3, 5]` in `x` and `[.3, .7]` in `p` were a single object, and as if we had `x.shape = (2,)`, `n.shape = (2,)`, and `p.shape = ()`. To obtain the individual elements without broadcasting, we would do this:

```
>>> multinomial.pmf([3, 4], n=7, p=[.3, .7])
0.2268945
>>> multinomial.pmf([3, 5], 8, p=[.3, .7])
0.25412184
```

This broadcasting also works for `cov`, where the output objects are square matrices of size `p.shape[-1]`. For example:

```
>>> multinomial.cov([4, 5], [[.3, .7], [.4, .6]])
array([[[0.84, -0.84],
 [-0.84, 0.84]],
 [[1.2 , -1.2],
 [-1.2 , 1.2]]])
```

In this example, `n.shape == (2,)` and `p.shape == (2, 2)`, and following the rules above, these broadcast as if `p.shape == (2,)`. Thus the result should also be of shape `(2,)`, but since each output is a  $2 \times 2$  matrix, the result in fact has shape `(2, 2, 2)`, where `result[0]` is equal to `multinomial.cov(n=4, p=[.3, .7])` and `result[1]` is equal to `multinomial.cov(n=5, p=[.4, .6])`.

## Methods

“ <code>pmf(x, n, p)</code> ”	Probability mass function.
“ <code>logpmf(x, n, p)</code> ”	Log of the probability mass function.
“ <code>rvs(n, p, size=1, random_state=None)</code> ”	Draw random samples from a multinomial distribution.
“ <code>entropy(n, p)</code> ”	Compute the entropy of the multinomial distribution.
“ <code>cov(n, p)</code> ”	Compute the covariance matrix of the multinomial distribution.

## scipy.stats.special\_ortho\_group

`scipy.stats.special_ortho_group = <scipy.stats._multivariate.special_ortho_group_gen object>`

A matrix-valued  $SO(N)$  random variable.

Return a random rotation matrix, drawn from the Haar distribution (the only uniform distribution on  $SO(n)$ ).

The `dim` keyword specifies the dimension  $N$ .

### Parameters

**dim** [scalar] Dimension of matrices

## Notes

This class is wrapping the `random_rot` code from the MDP Toolkit, <https://github.com/mdp-toolkit/mdp-toolkit>

Return a random rotation matrix, drawn from the Haar distribution (the only uniform distribution on  $SO(n)$ ). The algorithm is described in the paper Stewart, G.W., “The efficient generation of random orthogonal matrices with an application to condition estimators”, *SIAM Journal on Numerical Analysis*, 17(3), pp. 403-409, 1980. For more information see [https://en.wikipedia.org/wiki/Orthogonal\\_matrix#Randomization](https://en.wikipedia.org/wiki/Orthogonal_matrix#Randomization)

See also the similar `ortho_group`.

## Examples

```
>>> from scipy.stats import special_ortho_group
>>> x = special_ortho_group.rvs(3)
```

```
>>> np.dot(x, x.T)
array([[1.00000000e+00, 1.13231364e-17, -2.86852790e-16],
 [1.13231364e-17, 1.00000000e+00, -1.46845020e-16],
 [-2.86852790e-16, -1.46845020e-16, 1.00000000e+00]])
```

```
>>> import scipy.linalg
>>> scipy.linalg.det(x)
1.0
```

This generates one random matrix from  $SO(3)$ . It is orthogonal and has a determinant of 1.

## Methods

<code>“rvs(dim=None, size=1, random_state=None)”</code>	Draw random samples from $SO(N)$ .
---------------------------------------------------------	------------------------------------

## `scipy.stats.ortho_group`

`scipy.stats.ortho_group` = `<scipy.stats._multivariate.ortho_group_gen object>`  
A matrix-valued  $O(N)$  random variable.

Return a random orthogonal matrix, drawn from the  $O(N)$  Haar distribution (the only uniform distribution on  $O(N)$ ).

The `dim` keyword specifies the dimension  $N$ .

### Parameters

**dim** [scalar] Dimension of matrices

## Notes

This class is closely related to `special_ortho_group`.

Some care is taken to avoid numerical error, as per the paper by Mezzadri.

## References

[1]

## Examples

```
>>> from scipy.stats import ortho_group
>>> x = ortho_group.rvs(3)
```

```
>>> np.dot(x, x.T)
array([[1.00000000e+00, 1.13231364e-17, -2.86852790e-16],
 [1.13231364e-17, 1.00000000e+00, -1.46845020e-16],
 [-2.86852790e-16, -1.46845020e-16, 1.00000000e+00]])
```

```
>>> import scipy.linalg
>>> np.fabs(scipy.linalg.det(x))
1.0
```

This generates one random matrix from  $O(3)$ . It is orthogonal and has a determinant of +1 or -1.

## Methods

“ <code>rvs(dim=None, size=1, random_state=None)</code> “	Draw random samples from $O(N)$ .
-----------------------------------------------------------	-----------------------------------

## scipy.stats.unitary\_group

`scipy.stats.unitary_group` = <`scipy.stats._multivariate.unitary_group_gen` object>  
A matrix-valued  $U(N)$  random variable.

Return a random unitary matrix.

The *dim* keyword specifies the dimension  $N$ .

### Parameters

**dim** [scalar] Dimension of matrices

## Notes

This class is similar to `ortho_group`.

## References

[1]

## Examples

```
>>> from scipy.stats import unitary_group
>>> x = unitary_group.rvs(3)
```

```
>>> np.dot(x, x.conj().T)
array([[1.00000000e+00, 1.13231364e-17, -2.86852790e-16],
 [1.13231364e-17, 1.00000000e+00, -1.46845020e-16],
 [-2.86852790e-16, -1.46845020e-16, 1.00000000e+00]])
```

This generates one random matrix from  $U(3)$ . The dot product confirms that it is unitary up to machine precision.

## Methods

<code>“rvs(dim=None, size=1, random_state=None)”</code>	Draw random samples from U(N).
---------------------------------------------------------	--------------------------------

### scipy.stats.random\_correlation

`scipy.stats.random_correlation = <scipy.stats._multivariate.random_correlation_gen object>`

A random correlation matrix.

Return a random correlation matrix, given a vector of eigenvalues.

The *eigs* keyword specifies the eigenvalues of the correlation matrix, and implies the dimension.

#### Parameters

**eigs** [1d ndarray] Eigenvalues of correlation matrix.

## Notes

Generates a random correlation matrix following a numerically stable algorithm spelled out by Davies & Higham. This algorithm uses a single O(N) similarity transformation to construct a symmetric positive semi-definite matrix, and applies a series of Givens rotations to scale it to have ones on the diagonal.

## References

[1]

## Examples

```
>>> from scipy.stats import random_correlation
>>> np.random.seed(514)
>>> x = random_correlation.rvs((.5, .8, 1.2, 1.5))
>>> x
array([[1. , -0.20387311, 0.18366501, -0.04953711],
 [-0.20387311, 1. , -0.24351129, 0.06703474],
 [0.18366501, -0.24351129, 1. , 0.38530195],
 [-0.04953711, 0.06703474, 0.38530195, 1.]])
>>> import scipy.linalg
>>> e, v = scipy.linalg.eigh(x)
>>> e
array([0.5, 0.8, 1.2, 1.5])
```

## Methods

<code>“rvs(eigs=None, random_state=None)”</code>	Draw random correlation matrices, all with eigenvalues eigs.
--------------------------------------------------	--------------------------------------------------------------

## 6.28.6 Discrete distributions

<i>bernoulli</i>	A Bernoulli discrete random variable.
<i>binom</i>	A binomial discrete random variable.
<i>boltzmann</i>	A Boltzmann (Truncated Discrete Exponential) random variable.
<i>dlaplace</i>	A Laplacian discrete random variable.
<i>geom</i>	A geometric discrete random variable.
<i>hypergeom</i>	A hypergeometric discrete random variable.
<i>logser</i>	A Logarithmic (Log-Series, Series) discrete random variable.
<i>nbinom</i>	A negative binomial discrete random variable.
<i>planck</i>	A Planck discrete exponential random variable.
<i>poisson</i>	A Poisson discrete random variable.
<i>randint</i>	A uniform discrete random variable.
<i>skellam</i>	A Skellam discrete random variable.
<i>zipf</i>	A Zipf discrete random variable.
<i>yulesimon</i>	A Yule-Simon discrete random variable.

### scipy.stats.bernoulli

`scipy.stats.bernoulli` = <`scipy.stats._discrete_distns.bernoulli_gen` object>

A Bernoulli discrete random variable.

As an instance of the *rv\_discrete* class, *bernoulli* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

#### Notes

The probability mass function for *bernoulli* is:

$$f(k) = \begin{cases} 1 - p & \text{if } k = 0 \\ p & \text{if } k = 1 \end{cases}$$

for  $k$  in  $\{0, 1\}$ .

*bernoulli* takes  $p$  as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `bernoulli.pmf(k, p, loc)` is identically equivalent to `bernoulli.pmf(k - loc, p)`.

#### Examples

```
>>> from scipy.stats import bernoulli
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> p = 0.3
>>> mean, var, skew, kurt = bernoulli.stats(p, moments='mvsk')
```

Display the probability mass function (pmf):

```

>>> x = np.arange(bernoulli.ppf(0.01, p),
... bernoulli.ppf(0.99, p))
>>> ax.plot(x, bernoulli.pmf(x, p), 'bo', ms=8, label='bernoulli pmf')
>>> ax.vlines(x, 0, bernoulli.pmf(x, p), colors='b', lw=5, alpha=0.5)

```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```

>>> rv = bernoulli(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

Check accuracy of cdf and ppf:

```

>>> prob = bernoulli.cdf(x, p)
>>> np.allclose(x, bernoulli.ppf(prob, p))
True

```

Generate random numbers:

```

>>> r = bernoulli.rvs(p, size=1000)

```

## Methods

<code>rvs(p, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, p, loc=0)</code>	Probability mass function.
<code>logpmf(k, p, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, p, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, p, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, p, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, p, loc=0)</code>	Log of the survival function.
<code>ppf(q, p, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, p, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(p, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(p, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(p,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(p, loc=0)</code>	Median of the distribution.
<code>mean(p, loc=0)</code>	Mean of the distribution.
<code>var(p, loc=0)</code>	Variance of the distribution.
<code>std(p, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, p, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.binom

`scipy.stats.binom` = <scipy.stats.\_discrete\_distns.binom\_gen object>

A binomial discrete random variable.

As an instance of the *rv\_discrete* class, *binom* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability mass function for *binom* is:

$$f(k) = \binom{n}{k} p^k (1-p)^{n-k}$$

for  $k$  in  $\{0, 1, \dots, n\}$ .

*binom* takes  $n$  and  $p$  as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `binom.pmf(k, n, p, loc)` is identically equivalent to `binom.pmf(k - loc, n, p)`.

## Examples

```
>>> from scipy.stats import binom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> n, p = 5, 0.4
>>> mean, var, skew, kurt = binom.stats(n, p, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(binom.ppf(0.01, n, p),
... binom.ppf(0.99, n, p))
>>> ax.plot(x, binom.pmf(x, n, p), 'bo', ms=8, label='binom pmf')
>>> ax.vlines(x, 0, binom.pmf(x, n, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = binom(n, p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = binom.cdf(x, n, p)
>>> np.allclose(x, binom.ppf(prob, n, p))
True
```

Generate random numbers:

```
>>> r = binom.rvs(n, p, size=1000)
```

## Methods

<code>rvs(n, p, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, n, p, loc=0)</code>	Probability mass function.
<code>logpmf(k, n, p, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, n, p, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, n, p, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, n, p, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, n, p, loc=0)</code>	Log of the survival function.
<code>ppf(q, n, p, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, n, p, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(n, p, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(n, p, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(n, p), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(n, p, loc=0)</code>	Median of the distribution.
<code>mean(n, p, loc=0)</code>	Mean of the distribution.
<code>var(n, p, loc=0)</code>	Variance of the distribution.
<code>std(n, p, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, n, p, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.boltzmann

`scipy.stats.boltzmann` = <`scipy.stats._discrete_distns.boltzmann_gen` object>  
 A Boltzmann (Truncated Discrete Exponential) random variable.

As an instance of the *rv\_discrete* class, *boltzmann* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability mass function for *boltzmann* is:

$$f(k) = (1 - \exp(-\lambda)) \exp(-\lambda k) / (1 - \exp(-\lambda N))$$

for  $k = 0, \dots, N - 1$ .

*boltzmann* takes  $\lambda > 0$  and  $N > 0$  as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `boltzmann.pmf(k, lambda_, N, loc)` is identically equivalent to `boltzmann.pmf(k - loc, lambda_, N)`.

## Examples

```
>>> from scipy.stats import boltzmann
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> lambda_, N = 1.4, 19
>>> mean, var, skew, kurt = boltzmann.stats(lambda_, N, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(boltzmann.ppf(0.01, lambda_, N),
... boltzmann.ppf(0.99, lambda_, N))
>>> ax.plot(x, boltzmann.pmf(x, lambda_, N), 'bo', ms=8, label='boltzmann_
→pmf')
>>> ax.vlines(x, 0, boltzmann.pmf(x, lambda_, N), colors='b', lw=5,
→alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = boltzmann(lambda_, N)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = boltzmann.cdf(x, lambda_, N)
>>> np.allclose(x, boltzmann.ppf(prob, lambda_, N))
True
```

Generate random numbers:

```
>>> r = boltzmann.rvs(lambda_, N, size=1000)
```

## Methods

<code>rvs(lambda_, N, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, lambda_, N, loc=0)</code>	Probability mass function.
<code>logpmf(k, lambda_, N, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, lambda_, N, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, lambda_, N, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, lambda_, N, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, lambda_, N, loc=0)</code>	Log of the survival function.
<code>ppf(q, lambda_, N, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, lambda_, N, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(lambda_, N, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(lambda_, N, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(lambda_, N), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(lambda_, N, loc=0)</code>	Median of the distribution.
<code>mean(lambda_, N, loc=0)</code>	Mean of the distribution.
<code>var(lambda_, N, loc=0)</code>	Variance of the distribution.
<code>std(lambda_, N, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, lambda_, N, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.dlaplace

`scipy.stats.dlaplace` = <`scipy.stats._discrete_distns.dlaplace_gen` object>  
 A Laplacian discrete random variable.

As an instance of the *rv\_discrete* class, *dlaplace* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability mass function for *dlaplace* is:

$$f(k) = \tanh(a/2) \exp(-a|k|)$$

for integers  $k$  and  $a > 0$ .

*dlaplace* takes  $a$  as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `dlaplace.pmf(k, a, loc)` is identically equivalent to `dlaplace.pmf(k - loc, a)`.

## Examples

```
>>> from scipy.stats import dlaplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 0.8
>>> mean, var, skew, kurt = dlaplace.stats(a, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(dlaplace.ppf(0.01, a),
... dlaplace.ppf(0.99, a))
>>> ax.plot(x, dlaplace.pmf(x, a), 'bo', ms=8, label='dlaplace pmf')
>>> ax.vlines(x, 0, dlaplace.pmf(x, a), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = dlaplace(a)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = dlaplace.cdf(x, a)
>>> np.allclose(x, dlaplace.ppf(prob, a))
True
```

Generate random numbers:

```
>>> r = dlaplace.rvs(a, size=1000)
```

## Methods

<code>rvs(a, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, a, loc=0)</code>	Probability mass function.
<code>logpmf(k, a, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, a, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, a, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, a, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, a, loc=0)</code>	Log of the survival function.
<code>ppf(q, a, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(a, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(a,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0)</code>	Median of the distribution.
<code>mean(a, loc=0)</code>	Mean of the distribution.
<code>var(a, loc=0)</code>	Variance of the distribution.
<code>std(a, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.geom

`scipy.stats.geom` = <`scipy.stats._discrete_distns.geom_gen` object>

A geometric discrete random variable.

As an instance of the *rv\_discrete* class, *geom* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

*planck*

## Notes

The probability mass function for *geom* is:

$$f(k) = (1 - p)^{k-1} p$$

for  $k \geq 1$ .

*geom* takes *p* as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `geom.pmf(k, p, loc)` is identically equivalent to `geom.pmf(k - loc, p)`.

## Examples

```
>>> from scipy.stats import geom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> p = 0.5
>>> mean, var, skew, kurt = geom.stats(p, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(geom.ppf(0.01, p),
... geom.ppf(0.99, p))
>>> ax.plot(x, geom.pmf(x, p), 'bo', ms=8, label='geom pmf')
>>> ax.vlines(x, 0, geom.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = geom(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = geom.cdf(x, p)
>>> np.allclose(x, geom.ppf(prob, p))
True
```

Generate random numbers:

```
>>> r = geom.rvs(p, size=1000)
```

## Methods

<code>rvs(p, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, p, loc=0)</code>	Probability mass function.
<code>logpmf(k, p, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, p, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, p, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, p, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, p, loc=0)</code>	Log of the survival function.
<code>ppf(q, p, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, p, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(p, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(p, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(p,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(p, loc=0)</code>	Median of the distribution.
<code>mean(p, loc=0)</code>	Mean of the distribution.
<code>var(p, loc=0)</code>	Variance of the distribution.
<code>std(p, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, p, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.hypergeom

`scipy.stats.hypergeom` = <`scipy.stats._discrete_distns.hypergeom_gen` object>

A hypergeometric discrete random variable.

The hypergeometric distribution models drawing objects from a bin.  $M$  is the total number of objects,  $n$  is total number of Type I objects. The random variate represents the number of Type I objects in  $N$  drawn without replacement from the total population.

As an instance of the `rv_discrete` class, `hypergeom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The symbols used to denote the shape parameters ( $M$ ,  $n$ , and  $N$ ) are not universally accepted. See the Examples for a clarification of the definitions used here.

The probability mass function is defined as,

$$p(k, M, n, N) = \frac{\binom{n}{k} \binom{M-n}{N-k}}{\binom{M}{N}}$$

for  $k \in [\max(0, N - M + n), \min(n, N)]$ , where the binomial coefficients are defined as,

$$\binom{n}{k} \equiv \frac{n!}{k!(n-k)!}$$

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `hypergeom.pmf(k, M, n, N, loc)` is identically equivalent to `hypergeom.pmf(k - loc, M, n, N)`.

## Examples

```
>>> from scipy.stats import hypergeom
>>> import matplotlib.pyplot as plt
```

Suppose we have a collection of 20 animals, of which 7 are dogs. Then if we want to know the probability of finding a given number of dogs if we choose at random 12 of the 20 animals, we can initialize a frozen distribution and plot the probability mass function:

```
>>> [M, n, N] = [20, 7, 12]
>>> rv = hypergeom(M, n, N)
>>> x = np.arange(0, n+1)
>>> pmf_dogs = rv.pmf(x)
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, pmf_dogs, 'bo')
>>> ax.vlines(x, 0, pmf_dogs, lw=2)
>>> ax.set_xlabel('# of dogs in our group of chosen animals')
>>> ax.set_ylabel('hypergeom PMF')
>>> plt.show()
```

Instead of using a frozen distribution we can also use `hypergeom` methods directly. To for example obtain the cumulative distribution function, use:

```
>>> prb = hypergeom.cdf(x, M, n, N)
```

And to generate random numbers:

```
>>> R = hypergeom.rvs(M, n, N, size=10)
```

## Methods

<code>rvs(M, n, N, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, M, n, N, loc=0)</code>	Probability mass function.
<code>logpmf(k, M, n, N, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, M, n, N, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, M, n, N, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, M, n, N, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, M, n, N, loc=0)</code>	Log of the survival function.
<code>ppf(q, M, n, N, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, M, n, N, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(M, n, N, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(M, n, N, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(M, n, N), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(M, n, N, loc=0)</code>	Median of the distribution.
<code>mean(M, n, N, loc=0)</code>	Mean of the distribution.
<code>var(M, n, N, loc=0)</code>	Variance of the distribution.
<code>std(M, n, N, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, M, n, N, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.logser

`scipy.stats.logser` = <`scipy.stats._discrete_distns.logser_gen` object>

A Logarithmic (Log-Series, Series) discrete random variable.

As an instance of the `rv_discrete` class, `logser` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability mass function for `logser` is:

$$f(k) = -\frac{p^k}{k \log(1-p)}$$

for  $k \geq 1$ .

`logser` takes  $p$  as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `logser.pmf(k, p, loc)` is identically equivalent to `logser.pmf(k - loc, p)`.

## Examples

```
>>> from scipy.stats import logser
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> p = 0.6
>>> mean, var, skew, kurt = logser.stats(p, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(logser.ppf(0.01, p),
... logser.ppf(0.99, p))
>>> ax.plot(x, logser.pmf(x, p), 'bo', ms=8, label='logser pmf')
>>> ax.vlines(x, 0, logser.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = logser(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = logser.cdf(x, p)
>>> np.allclose(x, logser.ppf(prob, p))
True
```

Generate random numbers:

```
>>> r = logser.rvs(p, size=1000)
```

## Methods

<code>rvs(p, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, p, loc=0)</code>	Probability mass function.
<code>logpmf(k, p, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, p, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, p, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, p, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, p, loc=0)</code>	Log of the survival function.
<code>ppf(q, p, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, p, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(p, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(p, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(p,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(p, loc=0)</code>	Median of the distribution.
<code>mean(p, loc=0)</code>	Mean of the distribution.
<code>var(p, loc=0)</code>	Variance of the distribution.
<code>std(p, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, p, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.nbinom

`scipy.stats.nbinom` = <`scipy.stats._discrete_distns.nbinom_gen` object>

A negative binomial discrete random variable.

As an instance of the *rv\_discrete* class, *nbinom* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

Negative binomial distribution describes a sequence of i.i.d. Bernoulli trials, repeated until a predefined, non-random number of successes occurs.

The probability mass function of the number of failures for *nbinom* is:

$$f(k) = \binom{k+n-1}{n-1} p^n (1-p)^k$$

for  $k \geq 0$ .

*nbinom* takes *n* and *p* as shape parameters where *n* is the number of successes, whereas *p* is the probability of a single success.

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `nbinom.pmf(k, n, p, loc)` is identically equivalent to `nbinom.pmf(k - loc, n, p)`.

## Examples

```
>>> from scipy.stats import nbinom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> n, p = 0.4, 0.4
>>> mean, var, skew, kurt = nbinom.stats(n, p, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(nbinom.ppf(0.01, n, p),
... nbinom.ppf(0.99, n, p))
>>> ax.plot(x, nbinom.pmf(x, n, p), 'bo', ms=8, label='nbinom pmf')
>>> ax.vlines(x, 0, nbinom.pmf(x, n, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = nbinom(n, p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = nbinom.cdf(x, n, p)
>>> np.allclose(x, nbinom.ppf(prob, n, p))
True
```

Generate random numbers:

```
>>> r = nbinom.rvs(n, p, size=1000)
```

## Methods

<b>rvs(n, p, loc=0, size=1, random_state=None)</b>	Random variates.
<b>pmf(k, n, p, loc=0)</b>	Probability mass function.
<b>logpmf(k, n, p, loc=0)</b>	Log of the probability mass function.

<b>std(n, p, loc=0)</b>	Standard deviation of the distribution.
<b>interval(alpha, n, p, loc=0)</b>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.planck

`scipy.stats.planck` = <`scipy.stats._discrete_distns.planck_gen` object>

A Planck discrete exponential random variable.

As an instance of the *rv\_discrete* class, *planck* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

**See also:**

*geom*

## Notes

The probability mass function for *planck* is:

$$f(k) = (1 - \exp(-\lambda)) \exp(-\lambda k)$$

for  $k \geq 0$  and  $\lambda > 0$ .

*planck* takes  $\lambda$  as shape parameter. The Planck distribution can be written as a geometric distribution (*geom*) with  $p = 1 - \exp(-\lambda)$  shifted by  $loc = -1$ .

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `planck.pmf(k, lambda_, loc)` is identically equivalent to `planck.pmf(k - loc, lambda_)`.

## Examples

```
>>> from scipy.stats import planck
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> lambda_ = 0.51
>>> mean, var, skew, kurt = planck.stats(lambda_, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(planck.ppf(0.01, lambda_),
... planck.ppf(0.99, lambda_))
>>> ax.plot(x, planck.pmf(x, lambda_), 'bo', ms=8, label='planck pmf')
>>> ax.vlines(x, 0, planck.pmf(x, lambda_), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = planck(lambda_)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = planck.cdf(x, lambda_)
>>> np.allclose(x, planck.ppf(prob, lambda_))
True
```

Generate random numbers:

```
>>> r = planck.rvs(lambda_, size=1000)
```

## Methods

<code>rvs(lambda_, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, lambda_, loc=0)</code>	Probability mass function.
<code>logpmf(k, lambda_, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, lambda_, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, lambda_, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, lambda_, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, lambda_, loc=0)</code>	Log of the survival function.
<code>ppf(q, lambda_, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, lambda_, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(lambda_, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(lambda_, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(lambda_), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(lambda_, loc=0)</code>	Median of the distribution.
<code>mean(lambda_, loc=0)</code>	Mean of the distribution.
<code>var(lambda_, loc=0)</code>	Variance of the distribution.
<code>std(lambda_, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, lambda_, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.poisson

`scipy.stats.poisson` = <`scipy.stats._discrete_distns.poisson_gen` object>

A Poisson discrete random variable.

As an instance of the *rv\_discrete* class, *poisson* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability mass function for *poisson* is:

$$f(k) = \exp(-\mu) \frac{\mu^k}{k!}$$

for  $k \geq 0$ .

*poisson* takes  $\mu$  as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `poisson.pmf(k, mu, loc)` is identically equivalent to `poisson.pmf(k - loc, mu)`.

## Examples

```
>>> from scipy.stats import poisson
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mu = 0.6
>>> mean, var, skew, kurt = poisson.stats(mu, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(poisson.ppf(0.01, mu),
... poisson.ppf(0.99, mu))
>>> ax.plot(x, poisson.pmf(x, mu), 'bo', ms=8, label='poisson pmf')
>>> ax.vlines(x, 0, poisson.pmf(x, mu), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = poisson(mu)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = poisson.cdf(x, mu)
>>> np.allclose(x, poisson.ppf(prob, mu))
True
```

Generate random numbers:

```
>>> r = poisson.rvs(mu, size=1000)
```

## Methods

<b>rvs(mu, loc=0, size=1, random_state=None)</b>	Random variates.
<b>pmf(k, mu, loc=0)</b>	Probability mass function.
<b>logpmf(k, mu, loc=0)</b>	Log of the probability mass function.
<b>cdf(k, mu, loc=0)</b>	Cumulative distribution function.
<b>logcdf(k, mu, loc=0)</b>	Log of the cumulative distribution function.
<b>sf(k, mu, loc=0)</b>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<b>logsf(k, mu, loc=0)</b>	Log of the survival function.
<b>ppf(q, mu, loc=0)</b>	Percent point function (inverse of <i>cdf</i> — percentiles).
<b>isf(q, mu, loc=0)</b>	Inverse survival function (inverse of <i>sf</i> ).
<b>stats(mu, loc=0, moments='mv')</b>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<b>entropy(mu, loc=0)</b>	(Differential) entropy of the RV.
<b>expect(func, args=(mu,), loc=0, lb=None, ub=None, conditional=False)</b>	Expected value of a function (of one argument) with respect to the distribution.
<b>median(mu, loc=0)</b>	Median of the distribution.
<b>mean(mu, loc=0)</b>	Mean of the distribution.
<b>var(mu, loc=0)</b>	Variance of the distribution.
<b>std(mu, loc=0)</b>	Standard deviation of the distribution.
<b>interval(alpha, mu, loc=0)</b>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.randint

`scipy.stats.randint` = <`scipy.stats._discrete_distns.randint_gen` object>

A uniform discrete random variable.

As an instance of the `rv_discrete` class, `randint` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability mass function for `randint` is:

$$f(k) = \frac{1}{\text{high} - \text{low}}$$

for  $k = \text{low}, \dots, \text{high} - 1$ .

`randint` takes `low` and `high` as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `randint.pmf(k, low, high, loc)` is identically equivalent to `randint.pmf(k - loc, low, high)`.

## Examples

```
>>> from scipy.stats import randint
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> low, high = 7, 31
>>> mean, var, skew, kurt = randint.stats(low, high, moments='mvsk')
```

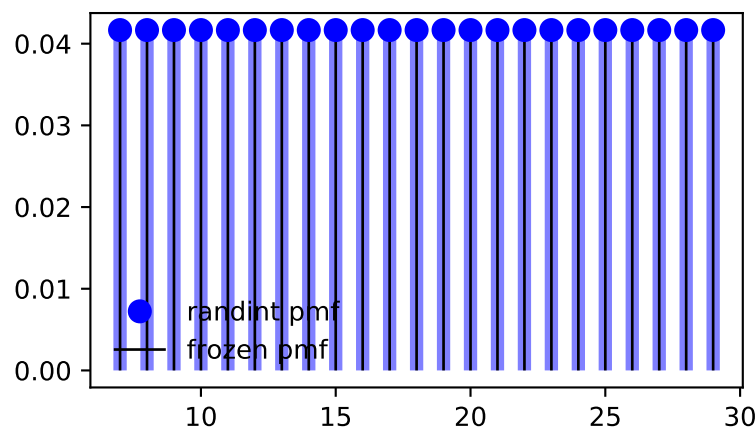

Display the probability mass function (pmf):

```
>>> x = np.arange(randint.ppf(0.01, low, high),
... randint.ppf(0.99, low, high))
>>> ax.plot(x, randint.pmf(x, low, high), 'bo', ms=8, label='randint pmf')
>>> ax.vlines(x, 0, randint.pmf(x, low, high), colors='b', lw=5, alpha=0.
→5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = randint(low, high)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = randint.cdf(x, low, high)
>>> np.allclose(x, randint.ppf(prob, low, high))
True
```

Generate random numbers:

```
>>> r = randint.rvs(low, high, size=1000)
```

## Methods

<b>rvs(low, high, loc=0, size=1, random_state=None)</b>	Random variates.
<b>pmf(k, low, high, loc=0)</b>	Probability mass function.
<b>logpmf(k, low, high, loc=0)</b>	Log of the probability mass function.
<b>cdf(k, low, high, loc=0)</b>	Cumulative distribution function.
<b>logcdf(k, low, high, loc=0)</b>	Log of the cumulative distribution function.
<b>sf(k, low, high, loc=0)</b>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<b>logsf(k, low, high, loc=0)</b>	Log of the survival function.
<b>ppf(q, low, high, loc=0)</b>	Percent point function (inverse of <i>cdf</i> — percentiles).
<b>isf(q, low, high, loc=0)</b>	Inverse survival function (inverse of <i>sf</i> ).
<b>stats(low, high, loc=0, moments='mv')</b>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<b>entropy(low, high, loc=0)</b>	(Differential) entropy of the RV.
<b>expect(func, args=(low, high), loc=0, lb=None, ub=None, conditional=False)</b>	Expected value of a function (of one argument) with respect to the distribution.
<b>median(low, high, loc=0)</b>	Median of the distribution.
<b>mean(low, high, loc=0)</b>	Mean of the distribution.
<b>var(low, high, loc=0)</b>	Variance of the distribution.
<b>std(low, high, loc=0)</b>	Standard deviation of the distribution.
<b>interval(alpha, low, high, loc=0)</b>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.skellam

`scipy.stats.skellam` = <`scipy.stats._discrete_distns.skellam_gen` object>

A Skellam discrete random variable.

As an instance of the `rv_discrete` class, `skellam` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

Probability distribution of the difference of two correlated or uncorrelated Poisson random variables.

Let  $k_1$  and  $k_2$  be two Poisson-distributed r.v. with expected values  $\lambda_1$  and  $\lambda_2$ . Then,  $k_1 - k_2$  follows a Skellam distribution with parameters  $\mu_1 = \lambda_1 - \rho\sqrt{\lambda_1\lambda_2}$  and  $\mu_2 = \lambda_2 - \rho\sqrt{\lambda_1\lambda_2}$ , where  $\rho$  is the correlation coefficient between  $k_1$  and  $k_2$ . If the two Poisson-distributed r.v. are independent then  $\rho = 0$ .

Parameters  $\mu_1$  and  $\mu_2$  must be strictly positive.

For details see: [https://en.wikipedia.org/wiki/Skellam\\_distribution](https://en.wikipedia.org/wiki/Skellam_distribution)

`skellam` takes  $\mu_1$  and  $\mu_2$  as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `skellam.pmf(k, mu1, mu2, loc)` is identically equivalent to `skellam.pmf(k - loc, mu1, mu2)`.

## Examples

```
>>> from scipy.stats import skellam
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> mu1, mu2 = 15, 8
>>> mean, var, skew, kurt = skellam.stats(mu1, mu2, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(skellam.ppf(0.01, mu1, mu2),
... skellam.ppf(0.99, mu1, mu2))
>>> ax.plot(x, skellam.pmf(x, mu1, mu2), 'bo', ms=8, label='skellam pmf')
>>> ax.vlines(x, 0, skellam.pmf(x, mu1, mu2), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = skellam(mu1, mu2)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = skellam.cdf(x, mu1, mu2)
>>> np.allclose(x, skellam.ppf(prob, mu1, mu2))
True
```

Generate random numbers:

```
>>> r = skellam.rvs(mu1, mu2, size=1000)
```

## Methods

<b>rvs(mu1, mu2, loc=0, size=1, random_state=None)</b>	Random variates.
<b>pmf(k, mu1, mu2, loc=0)</b>	Probability mass function.
<b>logpmf(k, mu1, mu2, loc=0)</b>	Log of the probability mass function.
<b>cdf(k, mu1, mu2, loc=0)</b>	Cumulative distribution function.
<b>logcdf(k, mu1, mu2, loc=0)</b>	Log of the cumulative distribution function.
<b>sf(k, mu1, mu2, loc=0)</b>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<b>logsf(k, mu1, mu2, loc=0)</b>	Log of the survival function.
<b>ppf(q, mu1, mu2, loc=0)</b>	Percent point function (inverse of <i>cdf</i> — percentiles).
<b>isf(q, mu1, mu2, loc=0)</b>	Inverse survival function (inverse of <i>sf</i> ).
<b>stats(mu1, mu2, loc=0, moments='mv')</b>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<b>entropy(mu1, mu2, loc=0)</b>	(Differential) entropy of the RV.
<b>expect(func, args=(mu1, mu2), loc=0, lb=None, ub=None, conditional=False)</b>	Expected value of a function (of one argument) with respect to the distribution.
<b>median(mu1, mu2, loc=0)</b>	Median of the distribution.
<b>mean(mu1, mu2, loc=0)</b>	Mean of the distribution.
<b>var(mu1, mu2, loc=0)</b>	Variance of the distribution.
<b>std(mu1, mu2, loc=0)</b>	Standard deviation of the distribution.
<b>interval(alpha, mu1, mu2, loc=0)</b>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.zipf

`scipy.stats.zipf = <scipy.stats._discrete_distns.zipf_gen object>`

A Zipf discrete random variable.

As an instance of the *rv\_discrete* class, *zipf* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability mass function for *zipf* is:

$$f(k, a) = \frac{1}{\zeta(a)k^a}$$

for  $k \geq 1$ .

`zipf` takes  $a$  as shape parameter.  $\zeta$  is the Riemann zeta function (`scipy.special.zeta`)

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `zipf.pmf(k, a, loc)` is identically equivalent to `zipf.pmf(k - loc, a)`.

## Examples

```
>>> from scipy.stats import zipf
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> a = 6.5
>>> mean, var, skew, kurt = zipf.stats(a, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(zipf.ppf(0.01, a),
... zipf.ppf(0.99, a))
>>> ax.plot(x, zipf.pmf(x, a), 'bo', ms=8, label='zipf pmf')
>>> ax.vlines(x, 0, zipf.pmf(x, a), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = zipf(a)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = zipf.cdf(x, a)
>>> np.allclose(x, zipf.ppf(prob, a))
True
```

Generate random numbers:

```
>>> r = zipf.rvs(a, size=1000)
```

## Methods

<code>rvs(a, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, a, loc=0)</code>	Probability mass function.
<code>logpmf(k, a, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, a, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, a, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, a, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, a, loc=0)</code>	Log of the survival function.
<code>ppf(q, a, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(a, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(a,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0)</code>	Median of the distribution.
<code>mean(a, loc=0)</code>	Mean of the distribution.
<code>var(a, loc=0)</code>	Variance of the distribution.
<code>std(a, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

## scipy.stats.yulesimon

`scipy.stats.yulesimon` = <scipy.stats.\_discrete\_distns.yulesimon\_gen object>

A Yule-Simon discrete random variable.

As an instance of the *rv\_discrete* class, *yulesimon* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

## Notes

The probability mass function for the *yulesimon* is:

$$f(k) = \alpha B(k, \alpha + 1)$$

for  $k = 1, 2, 3, \dots$ , where  $\alpha > 0$ . Here *B* refers to the `scipy.special.beta` function.

The sampling of random variates is based on pg 553, Section 6.3 of [1]. Our notation maps to the referenced logic via  $\alpha = a - 1$ .

For details see the wikipedia entry [2].

## References

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `yulesimon.pmf(k, alpha, loc)` is identically equivalent to `yulesimon.pmf(k - loc, alpha)`.

[1], [2]

## Examples

```
>>> from scipy.stats import yulesimon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate a few first moments:

```
>>> alpha = 11
>>> mean, var, skew, kurt = yulesimon.stats(alpha, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(yulesimon.ppf(0.01, alpha),
... yulesimon.ppf(0.99, alpha))
>>> ax.plot(x, yulesimon.pmf(x, alpha), 'bo', ms=8, label='yulesimon pmf')
>>> ax.vlines(x, 0, yulesimon.pmf(x, alpha), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = yulesimon(alpha)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
... label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = yulesimon.cdf(x, alpha)
>>> np.allclose(x, yulesimon.ppf(prob, alpha))
True
```

Generate random numbers:

```
>>> r = yulesimon.rvs(alpha, size=1000)
```

## Methods

<code>rvs(alpha, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, alpha, loc=0)</code>	Probability mass function.
<code>logpmf(k, alpha, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, alpha, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, alpha, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, alpha, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$ , but <i>sf</i> is sometimes more accurate).
<code>logsf(k, alpha, loc=0)</code>	Log of the survival function.
<code>ppf(q, alpha, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, alpha, loc=0)</code>	Inverse survival function (inverse of <i>sf</i> ).
<code>stats(alpha, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(alpha, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(alpha,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(alpha, loc=0)</code>	Median of the distribution.
<code>mean(alpha, loc=0)</code>	Mean of the distribution.
<code>var(alpha, loc=0)</code>	Variance of the distribution.
<code>std(alpha, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, alpha, loc=0)</code>	Endpoints of the range that contains alpha percent of the distribution

An overview of statistical functions is given below. Several of these functions have a similar version in `scipy.stats.mstats` which work for masked arrays.

### 6.28.7 Summary statistics

<code>describe(a[, axis, ddof, bias, nan_policy])</code>	Compute several descriptive statistics of the passed array.
<code>gmean(a[, axis, dtype])</code>	Compute the geometric mean along the specified axis.
<code>hmean(a[, axis, dtype])</code>	Calculate the harmonic mean along the specified axis.
<code>kurtosis(a[, axis, fisher, bias, nan_policy])</code>	Compute the kurtosis (Fisher or Pearson) of a dataset.
<code>mode(a[, axis, nan_policy])</code>	Return an array of the modal (most common) value in the passed array.
<code>moment(a[, moment, axis, nan_policy])</code>	Calculate the nth moment about the mean for a sample.
<code>skew(a[, axis, bias, nan_policy])</code>	Compute the sample skewness of a data set.
<code>kstat(data[, n])</code>	Return the nth k-statistic ( $1 \leq n \leq 4$ so far).
<code>kstatvar(data[, n])</code>	Returns an unbiased estimator of the variance of the k-statistic.
<code>tmean(a[, limits, inclusive, axis])</code>	Compute the trimmed mean.
<code>tvar(a[, limits, inclusive, axis, ddof])</code>	Compute the trimmed variance.
<code>tmin(a[, lowerlimit, axis, inclusive, ...])</code>	Compute the trimmed minimum.
<code>tmax(a[, upperlimit, axis, inclusive, ...])</code>	Compute the trimmed maximum.
<code>tstd(a[, limits, inclusive, axis, ddof])</code>	Compute the trimmed sample standard deviation.
<code>tsem(a[, limits, inclusive, axis, ddof])</code>	Compute the trimmed standard error of the mean.
<code>variation(a[, axis, nan_policy])</code>	Compute the coefficient of variation, the ratio of the biased standard deviation to the mean.
<code>find_repeats(arr)</code>	Find repeats and repeat counts.
<code>trim_mean(a, proportiontocut[, axis])</code>	Return mean of array after trimming distribution from both tails.
<code>gstd(a[, axis, ddof])</code>	Calculate the geometric standard deviation of an array
<code>iqr(x[, axis, rng, scale, nan_policy, ...])</code>	Compute the interquartile range of the data along the specified axis.
<code>sem(a[, axis, ddof, nan_policy])</code>	Calculate the standard error of the mean (or standard error of measurement) of the values in the input array.
<code>bayes_mvs(data[, alpha])</code>	Bayesian confidence intervals for the mean, var, and std.
<code>mvstdist(data)</code>	'Frozen' distributions for mean, variance, and standard deviation of data.
<code>entropy(pk[, qk, base])</code>	Calculate the entropy of a distribution for given probability values.
<code>median_absolute_deviation(x[, axis, center, ...])</code>	Compute the median absolute deviation of the data along the given axis.

### scipy.stats.describe

`scipy.stats.describe` (*a*, *axis=0*, *ddof=1*, *bias=True*, *nan\_policy='propagate'*)

Compute several descriptive statistics of the passed array.

#### Parameters

- a** [array\_like] Input data.
- axis** [int or None, optional] Axis along which statistics are calculated. Default is 0. If None, compute over the whole array *a*.
- ddof** [int, optional] Delta degrees of freedom (only for variance). Default is 1.
- bias** [bool, optional] If False, then the skewness and kurtosis calculations are corrected for statistical bias.
- nan\_policy** [{ 'propagate', 'raise', 'omit' }, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

#### Returns

<b>nobs</b>	[int or ndarray of ints] Number of observations (length of data along <i>axis</i> ). When 'omit' is chosen as <i>nan_policy</i> , each column is counted separately.
<b>minmax: tuple of ndarrays or floats</b>	Minimum and maximum value of data array.
<b>mean</b>	[ndarray or float] Arithmetic mean of data along axis.
<b>variance</b>	[ndarray or float] Unbiased variance of the data along axis, denominator is number of observations minus one.
<b>skewness</b>	[ndarray or float] Skewness, based on moment calculations with denominator equal to the number of observations, i.e. no degrees of freedom correction.
<b>kurtosis</b>	[ndarray or float] Kurtosis (Fisher). The kurtosis is normalized so that it is zero for the normal distribution. No degrees of freedom are used.

**See also:***skew, kurtosis***Examples**

```

>>> from scipy import stats
>>> a = np.arange(10)
>>> stats.describe(a)
DescribeResult(nobs=10, minmax=(0, 9), mean=4.5, variance=9.
→16666666666666666,
 skewness=0.0, kurtosis=-1.2242424242424244)
>>> b = [[1, 2], [3, 4]]
>>> stats.describe(b)
DescribeResult(nobs=2, minmax=(array([1, 2]), array([3, 4])),
 mean=array([2., 3.]), variance=array([2., 2.]),
 skewness=array([0., 0.]), kurtosis=array([-2., -2.]))

```

**scipy.stats.gmean**`scipy.stats.gmean(a, axis=0, dtype=None)`

Compute the geometric mean along the specified axis.

Return the geometric average of the array elements. That is:  $n$ -th root of  $(x_1 * x_2 * \dots * x_n)$ **Parameters**

<b>a</b>	[array_like] Input array or object that can be converted to an array.
<b>axis</b>	[int or None, optional] Axis along which the geometric mean is computed. Default is 0. If None, compute over the whole array <i>a</i> .
<b>dtype</b>	[dtype, optional] Type of the returned array and of the accumulator in which the elements are summed. If dtype is not specified, it defaults to the dtype of <i>a</i> , unless <i>a</i> has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

**Returns**

<b>gmean</b>	[ndarray] see dtype parameter above
--------------	-------------------------------------

**See also:***numpy.mean*

Arithmetic average

*numpy.average*

Weighted average

*hmean*

Harmonic mean

**Notes**

The geometric average is computed over a single dimension of the input array, `axis=0` by default, or all values in the array if `axis=None`. `float64` intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity because masked arrays automatically mask any non-finite values.

**Examples**

```
>>> from scipy.stats import gmean
>>> gmean([1, 4])
2.0
>>> gmean([1, 2, 3, 4, 5, 6, 7])
3.3800151591412964
```

**scipy.stats.hmean**`scipy.stats.hmean(a, axis=0, dtype=None)`

Calculate the harmonic mean along the specified axis.

That is:  $n / (1/x_1 + 1/x_2 + \dots + 1/x_n)$ **Parameters**

- a** [array\_like] Input array, masked array or object that can be converted to an array.
- axis** [int or None, optional] Axis along which the harmonic mean is computed. Default is 0. If None, compute over the whole array *a*.
- dtype** [dtype, optional] Type of the returned array and of the accumulator in which the elements are summed. If *dtype* is not specified, it defaults to the dtype of *a*, unless *a* has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

**Returns**

- hmean** [ndarray] see *dtype* parameter above

**See also:***numpy.mean*

Arithmetic average

*numpy.average*

Weighted average

*gmean*

Geometric mean

## Notes

The harmonic mean is computed over a single dimension of the input array, `axis=0` by default, or all values in the array if `axis=None`. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity.

## Examples

```
>>> from scipy.stats import hmean
>>> hmean([1, 4])
1.6000000000000001
>>> hmean([1, 2, 3, 4, 5, 6, 7])
2.6997245179063363
```

## scipy.stats.kurtosis

`scipy.stats.kurtosis(a, axis=0, fisher=True, bias=True, nan_policy='propagate')`

Compute the kurtosis (Fisher or Pearson) of a dataset.

Kurtosis is the fourth central moment divided by the square of the variance. If Fisher's definition is used, then 3.0 is subtracted from the result to give 0.0 for a normal distribution.

If `bias` is `False` then the kurtosis is calculated using k statistics to eliminate bias coming from biased moment estimators

Use `kurtosistest` to see if result is close enough to normal.

### Parameters

<b>a</b>	[array] data for which the kurtosis is calculated
<b>axis</b>	[int or None, optional] Axis along which the kurtosis is calculated. Default is 0. If None, compute over the whole array <i>a</i> .
<b>fisher</b>	[bool, optional] If True, Fisher's definition is used (normal ==> 0.0). If False, Pearson's definition is used (normal ==> 3.0).
<b>bias</b>	[bool, optional] If False, then the calculations are corrected for statistical bias.
<b>nan_policy</b>	[[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

### Returns

<b>kurtosis</b>	[array] The kurtosis of values along an axis. If all values are equal, return -3 for Fisher's definition and 0 for Pearson's definition.
-----------------	------------------------------------------------------------------------------------------------------------------------------------------

## References

[1]

## Examples

```
>>> from scipy.stats import kurtosis
>>> kurtosis([1, 2, 3, 4, 5])
-1.3
```

## scipy.stats.mode

`scipy.stats.mode` (*a*, *axis=0*, *nan\_policy='propagate'*)

Return an array of the modal (most common) value in the passed array.

If there is more than one such value, only the smallest is returned. The bin-count for the modal bins is also returned.

### Parameters

- a** [array\_like] n-dimensional array of which to find mode(s).
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

### Returns

- mode** [ndarray] Array of modal values.
- count** [ndarray] Array of counts for each mode.

## Examples

```
>>> a = np.array([[6, 8, 3, 0],
... [3, 2, 1, 7],
... [8, 1, 8, 4],
... [5, 3, 0, 5],
... [4, 7, 5, 9]])
>>> from scipy import stats
>>> stats.mode(a)
(array([[3, 1, 0, 0]]), array([[1, 1, 1, 1]]))
```

To get mode of whole array, specify `axis=None`:

```
>>> stats.mode(a, axis=None)
(array([3]), array([3]))
```

## scipy.stats.moment

`scipy.stats.moment` (*a*, *moment=1*, *axis=0*, *nan\_policy='propagate'*)

Calculate the *n*th moment about the mean for a sample.

A moment is a specific quantitative measure of the shape of a set of points. It is often used to calculate coefficients of skewness and kurtosis due to its close relationship with them.

### Parameters

**a** [array\_like] data

**moment** [int or array\_like of ints, optional] order of central moment that is returned. Default is 1.

**axis** [int or None, optional] Axis along which the central moment is computed. Default is 0. If None, compute over the whole array *a*.

**nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns****n-th central moment**

[ndarray or float] The appropriate moment along the given axis or over all values if axis is None. The denominator for the moment calculation is the number of observations, no degrees of freedom correction is done.

**See also:**

*kurtosis*, *skew*, *describe*

**Notes**

The k-th central moment of a data sample is:

$$m_k = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^k$$

Where n is the number of samples and x-bar is the mean. This function uses exponentiation by squares [1] for efficiency.

**References**

[1]

**Examples**

```
>>> from scipy.stats import moment
>>> moment([1, 2, 3, 4, 5], moment=1)
0.0
>>> moment([1, 2, 3, 4, 5], moment=2)
2.0
```

**scipy.stats.skew**

`scipy.stats.skew(a, axis=0, bias=True, nan_policy='propagate')`

Compute the sample skewness of a data set.

For normally distributed data, the skewness should be about 0. For unimodal continuous distributions, a skewness value > 0 means that there is more weight in the right tail of the distribution. The function *skewtest* can be used to determine if the skewness value is close enough to 0, statistically speaking.

**Parameters**

**a** [ndarray] data

**axis** [int or None, optional] Axis along which skewness is calculated. Default is 0. If None, compute over the whole array *a*.

**bias** [bool, optional] If False, then the calculations are corrected for statistical bias.

**nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

**skewness** [ndarray] The skewness of values along an axis, returning 0 where all values are equal.

**Notes**

The sample skewness is computed as the Fisher-Pearson coefficient of skewness, i.e.

$$g_1 = \frac{m_3}{m_2^{3/2}}$$

where

$$m_i = \frac{1}{N} \sum_{n=1}^N (x[n] - \bar{x})^i$$

is the biased sample *i*th central moment, and  $\bar{x}$  is the sample mean. If `bias` is False, the calculations are corrected for bias and the value computed is the adjusted Fisher-Pearson standardized moment coefficient, i.e.

$$G_1 = \frac{k_3}{k_2^{3/2}} = \frac{\sqrt{N(N-1)}}{N-2} \frac{m_3}{m_2^{3/2}}$$

**References**

[1]

**Examples**

```
>>> from scipy.stats import skew
>>> skew([1, 2, 3, 4, 5])
0.0
>>> skew([2, 8, 0, 4, 1, 9, 9, 0])
0.2650554122698573
```

**scipy.stats.kstat**

`scipy.stats.kstat` (*data*, *n*=2)  
Return the *n*th k-statistic (1<=*n*<=4 so far).

The *n*th k-statistic `k_n` is the unique symmetric unbiased estimator of the *n*th cumulant `kappa_n`.

**Parameters**

**data** [array\_like] Input array. Note that n-D input gets flattened.

**n** [int, {1, 2, 3, 4}, optional] Default is equal to 2.

**Returns****kstat** [float] The nth k-statistic.**See also:****kstatvar**

Returns an unbiased estimator of the variance of the k-statistic.

**moment**

Returns the n-th central moment about the mean for a sample.

**Notes**For a sample size  $n$ , the first few k-statistics are given by:

$$k_1 = \mu k_2 = \frac{n}{n-1} m_2 k_3 = \frac{n^2}{(n-1)(n-2)} m_3 k_4 = \frac{n^2[(n+1)m_4 - 3(n-1)m_2^2]}{(n-1)(n-2)(n-3)}$$

where  $\mu$  is the sample mean,  $m_2$  is the sample variance, and  $m_i$  is the i-th sample central moment.**References**<http://mathworld.wolfram.com/k-Statistic.html><http://mathworld.wolfram.com/Cumulant.html>**Examples**

```
>>> from scipy import stats
>>> rndm = np.random.RandomState(1234)
```

As sample size increases, n-th moment and n-th k-statistic converge to the same number (although they aren't identical). In the case of the normal distribution, they converge to zero.

```
>>> for n in [2, 3, 4, 5, 6, 7]:
... x = rndm.normal(size=10**n)
... m, k = stats.moment(x, 3), stats.kstat(x, 3)
... print("%0.3g %0.3g %0.3g" % (m, k, m-k))
-0.631 -0.651 0.0194
0.0282 0.0283 -8.49e-05
-0.0454 -0.0454 1.36e-05
7.53e-05 7.53e-05 -2.26e-09
0.00166 0.00166 -4.99e-09
-2.88e-06 -2.88e-06 8.63e-13
```

**scipy.stats.kstatvar**`scipy.stats.kstatvar` (*data*, *n=2*)

Returns an unbiased estimator of the variance of the k-statistic.

See `kstat` for more details of the k-statistic.

**Parameters**

**data** [array\_like] Input array. Note that n-D input gets flattened.  
**n** [int, {1, 2}, optional] Default is equal to 2.

**Returns**

**kstatvar** [float] The nth k-statistic variance.

**See also:**

**kstat**

Returns the n-th k-statistic.

**moment**

Returns the n-th central moment about the mean for a sample.

**Notes**

The variances of the first few k-statistics are given by:

$$\text{var}(k_1) = \frac{\kappa^2}{n} \text{var}(k_2) = \frac{\kappa^4}{n} + \frac{2\kappa_2^2}{n-1} \text{var}(k_3) = \frac{\kappa^6}{n} + \frac{9\kappa_2\kappa_4}{n-1} + \frac{9\kappa_3^2}{n-1} + \frac{6n\kappa_2^3}{(n-1)(n-2)} \text{var}(k_4) = \frac{\kappa^8}{n} + \frac{16\kappa_2\kappa_6}{n-1} + \frac{48\kappa_3\kappa_5}{n-1}$$

**scipy.stats.tmean**

`scipy.stats.tmean(a, limits=None, inclusive=(True, True), axis=None)`

Compute the trimmed mean.

This function finds the arithmetic mean of given values, ignoring values outside the given *limits*.

**Parameters**

**a** [array\_like] Array of values.  
**limits** [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None (default), then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval.  
**inclusive** [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).  
**axis** [int or None, optional] Axis along which to compute test. Default is None.

**Returns**

**tmean** [float]

**See also:**

**trim\_mean**

returns mean after trimming a proportion from both tails.

**Examples**

```

>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmean(x)
9.5
>>> stats.tmean(x, (3,17))
10.0

```

### scipy.stats.tvar

`scipy.stats.tvar` (*a*, *limits=None*, *inclusive=(True, True)*, *axis=0*, *ddof=1*)

Compute the trimmed variance.

This function computes the sample variance of an array of values, while ignoring values which are outside of given *limits*.

#### Parameters

- a** [array\_like] Array of values.
- limits** [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When *limits* is *None*, then all values are used. Either of the limit values in the tuple can also be *None* representing a half-open interval. The default value is *None*.
- inclusive** [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- axis** [int or None, optional] Axis along which to operate. Default is 0. If *None*, compute over the whole array *a*.
- ddof** [int, optional] Delta degrees of freedom. Default is 1.

#### Returns

- tvar** [float] Trimmed variance.

#### Notes

*tvar* computes the unbiased sample variance, i.e. it uses a correction factor  $n / (n - 1)$ .

#### Examples

```

>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tvar(x)
35.0
>>> stats.tvar(x, (3,17))
20.0

```

### scipy.stats.tmin

`scipy.stats.tmin` (*a*, *lowerlimit=None*, *axis=0*, *inclusive=True*, *nan\_policy='propagate'*)

Compute the trimmed minimum.

This function finds the minimum value of an array *a* along the specified axis, but only considering values greater than a specified lower limit.

**Parameters**

- a** [array\_like] array of values
- lowerlimit** [None or float, optional] Values in the input array less than the given limit will be ignored. When lowerlimit is None, then all values are used. The default value is None.
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- inclusive** [{True, False}, optional] This flag determines whether values exactly equal to the lower limit are included. The default value is True.
- nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- tmin** [float, int or ndarray]

**Examples**

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmin(x)
0
```

```
>>> stats.tmin(x, 13)
13
```

```
>>> stats.tmin(x, 13, inclusive=False)
14
```

**scipy.stats.tmax**

`scipy.stats.tmax` (*a*, *upperlimit=None*, *axis=0*, *inclusive=True*, *nan\_policy='propagate'*)

Compute the trimmed maximum.

This function computes the maximum value of an array along a given axis, while ignoring values larger than a specified upper limit.

**Parameters**

- a** [array\_like] array of values
- upperlimit** [None or float, optional] Values in the input array greater than the given limit will be ignored. When upperlimit is None, then all values are used. The default value is None.
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- inclusive** [{True, False}, optional] This flag determines whether values exactly equal to the upper limit are included. The default value is True.

**nan\_policy**

[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

**tmax** [float, int or ndarray]

**Examples**

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmax(x)
19
```

```
>>> stats.tmax(x, 13)
13
```

```
>>> stats.tmax(x, 13, inclusive=False)
12
```

**scipy.stats.tstd**

`scipy.stats.tstd(a, limits=None, inclusive=(True, True), axis=0, ddof=1)`

Compute the trimmed sample standard deviation.

This function finds the sample standard deviation of given values, ignoring values outside the given *limits*.

**Parameters**

**a** [array\_like] array of values

**limits** [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When *limits* is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.

**inclusive** [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).

**axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.

**ddof** [int, optional] Delta degrees of freedom. Default is 1.

**Returns**

**tstd** [float]

**Notes**

*tstd* computes the unbiased sample standard deviation, i.e. it uses a correction factor  $n / (n - 1)$ .

## Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tstd(x)
5.9160797830996161
>>> stats.tstd(x, (3, 17))
4.4721359549995796
```

## scipy.stats.tsem

`scipy.stats.tsem(a, limits=None, inclusive=(True, True), axis=0, ddof=1)`

Compute the trimmed standard error of the mean.

This function finds the standard error of the mean for given values, ignoring values outside the given *limits*.

### Parameters

<b>a</b>	[array_like] array of values
<b>limits</b>	[None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.
<b>inclusive</b>	[(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
<b>axis</b>	[int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array <i>a</i> .
<b>ddof</b>	[int, optional] Delta degrees of freedom. Default is 1.

### Returns

**tsem** [float]

## Notes

*tsem* uses unbiased sample standard deviation, i.e. it uses a correction factor  $n / (n - 1)$ .

## Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tsem(x)
1.3228756555322954
>>> stats.tsem(x, (3, 17))
1.1547005383792515
```

## scipy.stats.variation

`scipy.stats.variation(a, axis=0, nan_policy='propagate')`

Compute the coefficient of variation, the ratio of the biased standard deviation to the mean.

**Parameters**

- a** [array\_like] Input array.
- axis** [int or None, optional] Axis along which to calculate the coefficient of variation. Default is 0. If None, compute over the whole array *a*.
- nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- variation** [ndarray] The calculated variation along the requested axis.

**References**

[1]

**Examples**

```
>>> from scipy.stats import variation
>>> variation([1, 2, 3, 4, 5])
0.47140452079103173
```

**scipy.stats.find\_repeats**

`scipy.stats.find_repeats(arr)`

Find repeats and repeat counts.

**Parameters**

- arr** [array\_like] Input array. This is cast to float64.

**Returns**

- values** [ndarray] The unique values from the (flattened) input that are repeated.
- counts** [ndarray] Number of times the corresponding 'value' is repeated.

**Notes**

In numpy >= 1.9 `numpy.unique` provides similar functionality. The main difference is that `find_repeats` only returns repeated values.

**Examples**

```
>>> from scipy import stats
>>> stats.find_repeats([2, 1, 2, 3, 2, 2, 5])
RepeatedResults(values=array([2.]), counts=array([4]))
```

```
>>> stats.find_repeats([[10, 20, 1, 2], [5, 5, 4, 4]])
RepeatedResults(values=array([4., 5.]), counts=array([2, 2]))
```

## scipy.stats.trim\_mean

`scipy.stats.trim_mean(a, proportiontocut, axis=0)`

Return mean of array after trimming distribution from both tails.

If `proportiontocut = 0.1`, slices off 'leftmost' and 'rightmost' 10% of scores. The input is sorted before slicing. Slices off less if proportion results in a non-integer slice index (i.e., conservatively slices off `proportiontocut`).

### Parameters

**a** [array\_like] Input array  
**proportiontocut** [float] Fraction to cut off of both tails of the distribution  
**axis** [int or None, optional] Axis along which the trimmed means are computed. Default is 0. If None, compute over the whole array *a*.

### Returns

**trim\_mean** [ndarray] Mean of trimmed array.

### See also:

[`trimboth`](#)

[`tmean`](#)

compute the trimmed mean ignoring values outside given *limits*.

### Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.trim_mean(x, 0.1)
9.5
>>> x2 = x.reshape(5, 4)
>>> x2
array([[0, 1, 2, 3],
 [4, 5, 6, 7],
 [8, 9, 10, 11],
 [12, 13, 14, 15],
 [16, 17, 18, 19]])
>>> stats.trim_mean(x2, 0.25)
array([8., 9., 10., 11.])
>>> stats.trim_mean(x2, 0.25, axis=1)
array([1.5, 5.5, 9.5, 13.5, 17.5])
```

## scipy.stats.gstd

`scipy.stats.gstd(a, axis=0, ddof=1)`

Calculate the geometric standard deviation of an array

The geometric standard deviation describes the spread of a set of numbers where the geometric mean is preferred. It is a multiplicative factor, and so a dimensionless quantity.

It is defined as the exponent of the standard deviation of  $\log(a)$ . Mathematically the population geometric standard deviation can be evaluated as:

```
gstd = exp(std(log(a)))
```

New in version 1.3.0.

#### Parameters

- a** [array\_like] An array like object containing the sample data.
- axis** [int, tuple or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- ddof** [int, optional] Degree of freedom correction in the calculation of the geometric standard deviation. Default is 1.

#### Returns

##### ndarray or float

An array of the geometric standard deviation. If *axis* is None or *a* is a 1d array a float is returned.

#### Notes

As the calculation requires the use of logarithms the geometric standard deviation only supports strictly positive values. Any non-positive or infinite values will raise a *ValueError*. The geometric standard deviation is sometimes confused with the exponent of the standard deviation,  $\exp(\text{std}(a))$ . Instead the geometric standard deviation is  $\exp(\text{std}(\log(a)))$ . The default value for *ddof* is different to the default value (0) used by other *ddof* containing functions, such as `np.std` and `np.nanstd`.

#### Examples

Find the geometric standard deviation of a log-normally distributed sample. Note that the standard deviation of the distribution is one, on a log scale this evaluates to approximately  $\exp(1)$ .

```
>>> from scipy.stats import gstd
>>> np.random.seed(123)
>>> sample = np.random.lognormal(mean=0, sigma=1, size=1000)
>>> gstd(sample)
2.7217860664589946
```

Compute the geometric standard deviation of a multidimensional array and of a given axis.

```
>>> a = np.arange(1, 25).reshape(2, 3, 4)
>>> gstd(a, axis=None)
2.2944076136018947
>>> gstd(a, axis=2)
array([[1.82424757, 1.22436866, 1.13183117],
 [1.09348306, 1.07244798, 1.05914985]])
>>> gstd(a, axis=(1,2))
array([2.12939215, 1.22120169])
```

The geometric standard deviation further handles masked arrays.

```
>>> a = np.arange(1, 25).reshape(2, 3, 4)
>>> ma = np.ma.masked_where(a > 16, a)
>>> ma
masked_array(
```

(continues on next page)

(continued from previous page)

```

data=[[1, 2, 3, 4],
 [5, 6, 7, 8],
 [9, 10, 11, 12]],
 [[13, 14, 15, 16],
 [--, --, --, --],
 [--, --, --, --]]],
mask=[[False, False, False, False],
 [False, False, False, False],
 [False, False, False, False]],
 [[False, False, False, False],
 [True, True, True, True],
 [True, True, True, True]]],
fill_value=999999)
>>> gstd(ma, axis=2)
masked_array(
 data=[[1.8242475707663655, 1.2243686572447428, 1.1318311657788478],
 [1.0934830582350938, --, --]],
 mask=[[False, False, False],
 [False, True, True]],
 fill_value=999999)

```

## scipy.stats.iqr

`scipy.stats.iqr(x, axis=None, rng=(25, 75), scale='raw', nan_policy='propagate', interpolation='linear', keepdims=False)`

Compute the interquartile range of the data along the specified axis.

The interquartile range (IQR) is the difference between the 75th and 25th percentile of the data. It is a measure of the dispersion similar to standard deviation or variance, but is much more robust against outliers [2].

The `rng` parameter allows this function to compute other percentile ranges than the actual IQR. For example, setting `rng=(0, 100)` is equivalent to `numpy.ptp`.

The IQR of an empty array is `np.nan`.

New in version 0.18.0.

### Parameters

- x** [array\_like] Input array or object that can be converted to an array.
- axis** [int or sequence of int, optional] Axis along which the range is computed. The default is to compute the IQR for the entire array.
- rng** [Two-element sequence containing floats in range of [0,100] optional] Percentiles over which to compute the range. Each must be between 0 and 100, inclusive. The default is the true IQR: (25, 75). The order of the elements is not important.
- scale** [scalar or str, optional] The numerical value of scale will be divided out of the final result. The following string values are recognized:  
     'raw': No scaling, just return the raw IQR. 'normal': Scale by  $2\sqrt{2}erf^{-1}(\frac{1}{2}) \approx 1.349$ .  
     The default is 'raw'. Array-like scale is also allowed, as long as it broadcasts correctly to the output such that `out / scale` is a valid operation. The output dimensions depend on the input array, `x`, the `axis` argument, and the `keepdims` flag.
- nan\_policy** [{"propagate", "raise", "omit"}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**interpolation**

[[‘linear’, ‘lower’, ‘higher’, ‘midpoint’, ‘nearest’], optional] Specifies the interpolation method to use when the percentile boundaries lie between two data points  $i$  and  $j$ :

- **‘linear’**  $[i + (j - i) * fraction]$ , where  $fraction$  is the fractional part of the index surrounded by  $i$  and  $j$ .
- ‘lower’:  $i$ .
- ‘higher’:  $j$ .
- ‘nearest’:  $i$  or  $j$  whichever is nearest.
- ‘midpoint’:  $(i + j) / 2$ .

Default is ‘linear’.

**keepdims** [bool, optional] If this is set to *True*, the reduced axes are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original array  $x$ .

**Returns**

**iqr** [scalar or ndarray] If `axis=None`, a scalar is returned. If the input contains integers or floats of smaller precision than `np.float64`, then the output data-type is `np.float64`. Otherwise, the output data-type is the same as that of the input.

**See also:**

`numpy.std`, `numpy.var`

**Notes**

This function is heavily dependent on the version of `numpy` that is installed. Versions greater than 1.11.0b3 are highly recommended, as they include a number of enhancements and fixes to `numpy.percentile` and `numpy.nanpercentile` that affect the operation of this function. The following modifications apply:

**Below 1.10.0**

[*nan\_policy* is poorly defined.] The default behavior of `numpy.percentile` is used for ‘propagate’. This is a hybrid of ‘omit’ and ‘propagate’ that mostly yields a skewed version of ‘omit’ since NaNs are sorted to the end of the data. A warning is raised if there are NaNs in the data.

**Below 1.9.0: `numpy.nanpercentile` does not exist.**

This means that `numpy.percentile` is used regardless of *nan\_policy* and a warning is issued. See previous item for a description of the behavior.

**Below 1.9.0: `keepdims` and `interpolation` are not supported.**

The keywords get ignored with a warning if supplied with non-default values. However, multiple axes are still supported.

**References**

[1], [2], [3]

**Examples**

```
>>> from scipy.stats import iqr
>>> x = np.array([[10, 7, 4], [3, 2, 1]])
>>> x
array([[10, 7, 4],
```

(continues on next page)

(continued from previous page)

```

 [3, 2, 1]])
>>> iqr(x)
4.0
>>> iqr(x, axis=0)
array([3.5, 2.5, 1.5])
>>> iqr(x, axis=1)
array([3., 1.])
>>> iqr(x, axis=1, keepdims=True)
array([[3.],
 [1.]])

```

## scipy.stats.sem

`scipy.stats.sem(a, axis=0, ddof=1, nan_policy='propagate')`

Calculate the standard error of the mean (or standard error of measurement) of the values in the input array.

### Parameters

- a** [array\_like] An array containing the values for which the standard error is returned.
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- ddof** [int, optional] Delta degrees-of-freedom. How many degrees of freedom to adjust for bias in limited samples relative to the population estimate of variance. Defaults to 1.
- nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

### Returns

- s** [ndarray or float] The standard error of the mean in the sample(s), along the input axis.

## Notes

The default value for *ddof* is different to the default (0) used by other *ddof* containing routines, such as `np.std` and `np.nanstd`.

## Examples

Find standard error along the first axis:

```

>>> from scipy import stats
>>> a = np.arange(20).reshape(5,4)
>>> stats.sem(a)
array([2.8284, 2.8284, 2.8284, 2.8284])

```

Find standard error across the whole array, using n degrees of freedom:

```

>>> stats.sem(a, axis=None, ddof=0)
1.2893796958227628

```

## scipy.stats.bayes\_mvs

`scipy.stats.bayes_mvs` (*data*, *alpha*=0.9)  
 Bayesian confidence intervals for the mean, var, and std.

### Parameters

- data** [array\_like] Input data, if multi-dimensional it is flattened to 1-D by `bayes_mvs`. Requires 2 or more data points.
- alpha** [float, optional] Probability that the returned confidence interval contains the true parameter.

### Returns

#### mean\_cntr, var\_cntr, std\_cntr

[tuple] The three results are for the mean, variance and standard deviation, respectively. Each result is a tuple of the form:

```
(center, (lower, upper))
```

with *center* the mean of the conditional pdf of the value given the data, and (*lower*, *upper*) a confidence interval, centered on the median, containing the estimate to a probability *alpha*.

### See also:

`mvsgdist`

### Notes

Each tuple of mean, variance, and standard deviation estimates represent the (center, (lower, upper)) with center the mean of the conditional pdf of the value given the data and (lower, upper) is a confidence interval centered on the median, containing the estimate to a probability *alpha*.

Converts data to 1-D and assumes all data has the same mean and variance. Uses Jeffrey's prior for variance and std.

Equivalent to `tuple((x.mean(), x.interval(alpha)) for x in mvsgdist(dat))`

### References

T.E. Oliphant, "A Bayesian perspective on estimating mean, variance, and standard-deviation from data", <https://scholarsarchive.byu.edu/facpub/278>, 2006.

### Examples

First a basic example to demonstrate the outputs:

```
>>> from scipy import stats
>>> data = [6, 9, 12, 7, 8, 8, 13]
>>> mean, var, std = stats.bayes_mvs(data)
>>> mean
Mean(statistic=9.0, minmax=(7.103650222612533, 10.896349777387467))
>>> var
Variance(statistic=10.0, minmax=(3.176724206..., 24.45910382...))
>>> std
Std_dev(statistic=2.9724954732045084, minmax=(1.7823367265645143, 4.
→945614605014631))
```

Now we generate some normally distributed random data, and get estimates of mean and standard deviation with 95% confidence intervals for those estimates:

```
>>> n_samples = 100000
>>> data = stats.norm.rvs(size=n_samples)
>>> res_mean, res_var, res_std = stats.bayes_mvs(data, alpha=0.95)
```

```
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.hist(data, bins=100, density=True, label='Histogram of data')
>>> ax.vlines(res_mean.statistic, 0, 0.5, colors='r', label='Estimated_
→mean')
>>> ax.axvspan(res_mean.minmax[0], res_mean.minmax[1], facecolor='r',
... alpha=0.2, label=r'Estimated mean (95% limits)')
>>> ax.vlines(res_std.statistic, 0, 0.5, colors='g', label='Estimated_
→scale')
>>> ax.axvspan(res_std.minmax[0], res_std.minmax[1], facecolor='g',
→alpha=0.2,
... label=r'Estimated scale (95% limits)')
```

```
>>> ax.legend(fontsize=10)
>>> ax.set_xlim([-4, 4])
>>> ax.set_ylim([0, 0.5])
>>> plt.show()
```

### scipy.stats.mvstdist

`scipy.stats.mvstdist` (*data*)

'Frozen' distributions for mean, variance, and standard deviation of data.

#### Parameters

**data** [array\_like] Input array. Converted to 1-D using `ravel`. Requires 2 or more data-points.

**Returns**

**mdist** ["frozen" distribution object] Distribution object representing the mean of the data  
**vdist** ["frozen" distribution object] Distribution object representing the variance of the data  
**sdist** ["frozen" distribution object] Distribution object representing the standard deviation of the data

**See also:**[\*bayes\\_mvs\*](#)**Notes**

The return values from `bayes_mvs(data)` is equivalent to `tuple((x.mean(), x.interval(0.90)) for x in mvstdist(data))`.

In other words, calling `<dist>.mean()` and `<dist>.interval(0.90)` on the three distribution objects returned from this function will give the same results that are returned from [\*bayes\\_mvs\*](#).

**References**

T.E. Oliphant, "A Bayesian perspective on estimating mean, variance, and standard-deviation from data", <https://scholarsarchive.byu.edu/facpub/278>, 2006.

**Examples**

```
>>> from scipy import stats
>>> data = [6, 9, 12, 7, 8, 8, 13]
>>> mean, var, std = stats.mvstdist(data)
```

We now have frozen distribution objects "mean", "var" and "std" that we can examine:

```
>>> mean.mean()
9.0
>>> mean.interval(0.95)
(6.6120585482655692, 11.387941451734431)
>>> mean.std()
1.1952286093343936
```

**scipy.stats.entropy**

`scipy.stats.entropy(pk, qk=None, base=None)`

Calculate the entropy of a distribution for given probability values.

If only probabilities  $pk$  are given, the entropy is calculated as  $S = -\sum(pk * \log(pk), axis=0)$ .

If  $qk$  is not None, then compute the Kullback-Leibler divergence  $S = \sum(pk * \log(pk / qk), axis=0)$ .

This routine will normalize  $pk$  and  $qk$  if they don't sum to 1.

**Parameters**

**pk** [sequence] Defines the (discrete) distribution. `pk[i]` is the (possibly unnormalized) probability of event  $i$ .

- pk** [sequence, optional] Sequence against which the relative entropy is computed. Should be in the same format as *pk*.
- base** [float, optional] The logarithmic base to use, defaults to  $e$  (natural logarithm).

**Returns**

- S** [float] The calculated entropy.

**scipy.stats.median\_absolute\_deviation**

`scipy.stats.median_absolute_deviation(x, axis=0, center=<function median>, scale=1.4826, nan_policy='propagate')`

Compute the median absolute deviation of the data along the given axis.

The median absolute deviation (MAD, [1]) computes the median over the absolute deviations from the median. It is a measure of dispersion similar to the standard deviation, but is more robust to outliers [2].

The MAD of an empty array is `np.nan`.

New in version 1.3.0.

**Parameters**

- x** [array\_like] Input array or object that can be converted to an array.
- axis** [int or None, optional] Axis along which the range is computed. Default is 0. If None, compute the MAD over the entire array.
- center** [callable, optional] A function that will return the central value. The default is to use `np.median`. Any user defined function used will need to have the function signature `func(arr, axis)`.
- scale** [int, optional] The scaling factor applied to the MAD. The default scale (1.4826) ensures consistency with the standard deviation for normally distributed data.
- nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- mad** [scalar or ndarray] If `axis=None`, a scalar is returned. If the input contains integers or floats of smaller precision than `np.float64`, then the output data-type is `np.float64`. Otherwise, the output data-type is the same as that of the input.

**See also:**

`numpy.std`, `numpy.var`, `numpy.median`, `scipy.stats.iqr`, `scipy.stats.tmean`, `scipy.stats.tstd`, `scipy.stats.tvar`

**Notes**

The *center* argument only affects the calculation of the central value around which the MAD is calculated. That is, passing in `center=np.mean` will calculate the MAD around the mean - it will not calculate the *mean* absolute deviation.

**References**

[1], [2]

## Examples

When comparing the behavior of `median_absolute_deviation` with `np.std`, the latter is affected when we change a single value of an array to have an outlier value while the MAD hardly changes:

```
>>> from scipy import stats
>>> x = stats.norm.rvs(size=100, scale=1, random_state=123456)
>>> x.std()
0.9973906394005013
>>> stats.median_absolute_deviation(x)
1.2280762773108278
>>> x[0] = 345.6
>>> x.std()
34.42304872314415
>>> stats.median_absolute_deviation(x)
1.2340335571164334
```

Axis handling example:

```
>>> x = np.array([[10, 7, 4], [3, 2, 1]])
>>> x
array([[10, 7, 4],
 [3, 2, 1]])
>>> stats.median_absolute_deviation(x)
array([5.1891, 3.7065, 2.2239])
>>> stats.median_absolute_deviation(x, axis=None)
2.9652
```

## 6.28.8 Frequency statistics

<code>cumfreq(a[, numbins, defaultreallimits, weights])</code>	Return a cumulative frequency histogram, using the histogram function.
<code>itemfreq(*args, **kwargs)</code>	<code>itemfreq</code> is deprecated! <code>itemfreq</code> is deprecated and will be removed in a future version.
<code>percentileofscore(a, score[, kind])</code>	The percentile rank of a score relative to a list of scores.
<code>scoreatpercentile(a, per[, limit, ...])</code>	Calculate the score at a given percentile of the input sequence.
<code>relfreq(a[, numbins, defaultreallimits, weights])</code>	Return a relative frequency histogram, using the histogram function.

### scipy.stats.cumfreq

`scipy.stats.cumfreq(a, numbins=10, defaultreallimits=None, weights=None)`

Return a cumulative frequency histogram, using the histogram function.

A cumulative histogram is a mapping that counts the cumulative number of observations in all of the bins up to the specified bin.

#### Parameters

- a** [array\_like] Input array.
- numbins** [int, optional] The number of bins to use for the histogram. Default is 10.
- defaultreallimits**

[tuple (lower, upper), optional] The lower and upper values for the range of the histogram. If no value is given, a range slightly larger than the range of the values in *a* is used. Specifically  $(a.\min() - s, a.\max() + s)$ , where  $s = (1/2)(a.\max() - a.\min()) / (\text{numbins} - 1)$ .

**weights** [array\_like, optional] The weights for each value in *a*. Default is None, which gives each value a weight of 1.0

### Returns

**cumcount** [ndarray] Binned values of cumulative frequency.

**lowerlimit** [float] Lower real limit

**binsize** [float] Width of each bin.

**extrapoints** [int] Extra points.

### Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy import stats
>>> x = [1, 4, 2, 1, 3, 1]
>>> res = stats.cumfreq(x, numbins=4, defaultreallimits=(1.5, 5))
>>> res.cumcount
array([1., 2., 3., 3.])
>>> res.extrapoints
3
```

Create a normal distribution with 1000 random values

```
>>> rng = np.random.RandomState(seed=12345)
>>> samples = stats.norm.rvs(size=1000, random_state=rng)
```

Calculate cumulative frequencies

```
>>> res = stats.cumfreq(samples, numbins=25)
```

Calculate space of values for x

```
>>> x = res.lowerlimit + np.linspace(0, res.binsize*res.cumcount.size,
... res.cumcount.size)
```

Plot histogram and cumulative histogram

```
>>> fig = plt.figure(figsize=(10, 4))
>>> ax1 = fig.add_subplot(1, 2, 1)
>>> ax2 = fig.add_subplot(1, 2, 2)
>>> ax1.hist(samples, bins=25)
>>> ax1.set_title('Histogram')
>>> ax2.bar(x, res.cumcount, width=res.binsize)
>>> ax2.set_title('Cumulative histogram')
>>> ax2.set_xlim([x.min(), x.max()])
```

```
>>> plt.show()
```

### scipy.stats.itemfreq

`scipy.stats.itemfreq(*args, **kwargs)`

*itemfreq* is deprecated! *itemfreq* is deprecated and will be removed in a future version. Use instead `np.unique(..., return_counts=True)`

Return a 2-D array of item frequencies.

#### Parameters

**a** [(N,) array\_like] Input array.

#### Returns

**itemfreq** [(K, 2) ndarray] A 2-D frequency table. Column 1 contains sorted, unique values from *a*, column 2 contains their respective counts.

### Examples

```
>>> from scipy import stats
>>> a = np.array([1, 1, 5, 0, 1, 2, 2, 0, 1, 4])
>>> stats.itemfreq(a)
array([[0., 2.],
 [1., 4.],
 [2., 2.],
 [4., 1.],
 [5., 1.]])
>>> np.bincount(a)
array([2, 4, 2, 0, 1, 1])
```

```
>>> stats.itemfreq(a/10.)
array([[0. , 2.],
 [0.1, 4.],
 [0.2, 2.],
 [0.4, 1.],
 [0.5, 1.]])
```

**scipy.stats.percentileofscore**

`scipy.stats.percentileofscore` (*a*, *score*, *kind*='rank')

The percentile rank of a score relative to a list of scores.

A *percentileofscore* of, for example, 80% means that 80% of the scores in *a* are below the given score. In the case of gaps or ties, the exact definition depends on the optional keyword, *kind*.

**Parameters**

- |              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>a</b>     | [array_like] Array of scores to which <i>score</i> is compared.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>score</b> | [int or float] Score that is compared to the elements in <i>a</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>kind</b>  | [{'rank', 'weak', 'strict', 'mean'}, optional] This optional parameter specifies the interpretation of the resulting score: <ul style="list-style-type: none"> <li>• <b>“rank”</b>: Average percentage ranking of score. In case of multiple matches, average the percentage rankings of all matching scores.</li> <li>• <b>“weak”</b>: This kind corresponds to the definition of a cumulative distribution function. A percentileofscore of 80% means that 80% of values are less than or equal to the provided score.</li> <li>• <b>“strict”</b>: Similar to “weak”, except that only values that are strictly less than the given score are counted.</li> <li>• <b>“mean”</b>: The average of the “weak” and “strict” scores, often used in testing. See <a href="https://en.wikipedia.org/wiki/Percentile_rank">https://en.wikipedia.org/wiki/Percentile_rank</a></li> </ul> |

**Returns**

- |             |                                                                     |
|-------------|---------------------------------------------------------------------|
| <b>pcos</b> | [float] Percentile-position of score (0-100) relative to <i>a</i> . |
|-------------|---------------------------------------------------------------------|

**See also:**

`numpy.percentile`

**Examples**

Three-quarters of the given values lie below a given score:

```
>>> from scipy import stats
>>> stats.percentileofscore([1, 2, 3, 4], 3)
75.0
```

With multiple matches, note how the scores of the two matches, 0.6 and 0.8 respectively, are averaged:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3)
70.0
```

Only 2/5 values are strictly less than 3:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='strict')
40.0
```

But 4/5 values are less than or equal to 3:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='weak')
80.0
```

The average between the weak and the strict scores is

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='mean')
60.0
```

## scipy.stats.scoreatpercentile

`scipy.stats.scoreatpercentile` (*a*, *per*, *limit*=(), *interpolation\_method*='fraction', *axis*=None)

Calculate the score at a given percentile of the input sequence.

For example, the score at *per*=50 is the median. If the desired quantile lies between two data points, we interpolate between them, according to the value of *interpolation*. If the parameter *limit* is provided, it should be a tuple (lower, upper) of two values.

### Parameters

- a** [array\_like] A 1-D array of values from which to extract score.
- per** [array\_like] Percentile(s) at which to extract score. Values should be in range [0,100].
- limit** [tuple, optional] Tuple of two scalars, the lower and upper limits within which to compute the percentile. Values of *a* outside this (closed) interval will be ignored.
- interpolation\_method** [{‘fraction’, ‘lower’, ‘higher’}, optional] This optional parameter specifies the interpolation method to use, when the desired quantile lies between two data points *i* and *j*
  - fraction:  $i + (j - i) * \text{fraction}$  where *fraction* is the fractional part of the index surrounded by *i* and *j*.
  - lower: *i*.
  - higher: *j*.
- axis** [int, optional] Axis along which the percentiles are computed. Default is None. If None, compute over the whole array *a*.

### Returns

- score** [float or ndarray] Score at percentile(s).

### See also:

[`percentileofscore`](#), [`numpy.percentile`](#)

### Notes

This function will become obsolete in the future. For NumPy 1.9 and higher, [`numpy.percentile`](#) provides all the functionality that [`scoreatpercentile`](#) provides. And it’s significantly faster. Therefore it’s recommended to use [`numpy.percentile`](#) for users that have `numpy >= 1.9`.

### Examples

```
>>> from scipy import stats
>>> a = np.arange(100)
>>> stats.scoreatpercentile(a, 50)
49.5
```

**scipy.stats.relfreq**

`scipy.stats.relfreq(a, numbins=10, defaultreallimits=None, weights=None)`

Return a relative frequency histogram, using the histogram function.

A relative frequency histogram is a mapping of the number of observations in each of the bins relative to the total of observations.

**Parameters**

- a** [array\_like] Input array.
- numbins** [int, optional] The number of bins to use for the histogram. Default is 10.
- defaultreallimits** [tuple (lower, upper), optional] The lower and upper values for the range of the histogram. If no value is given, a range slightly larger than the range of the values in *a* is used. Specifically  $(a.\text{min}() - s, a.\text{max}() + s)$ , where  $s = (1/2)(a.\text{max}() - a.\text{min}()) / (\text{numbins} - 1)$ .
- weights** [array\_like, optional] The weights for each value in *a*. Default is None, which gives each value a weight of 1.0

**Returns**

- frequency** [ndarray] Binned values of relative frequency.
- lowerlimit** [float] Lower real limit
- binsize** [float] Width of each bin.
- extrapoints** [int] Extra points.

**Examples**

```
>>> import matplotlib.pyplot as plt
>>> from scipy import stats
>>> a = np.array([2, 4, 1, 2, 3, 2])
>>> res = stats.relfreq(a, numbins=4)
>>> res.frequency
array([0.16666667, 0.5 , 0.16666667, 0.16666667])
>>> np.sum(res.frequency) # relative frequencies should add up to 1
1.0
```

Create a normal distribution with 1000 random values

```
>>> rng = np.random.RandomState(seed=12345)
>>> samples = stats.norm.rvs(size=1000, random_state=rng)
```

Calculate relative frequencies

```
>>> res = stats.relfreq(samples, numbins=25)
```

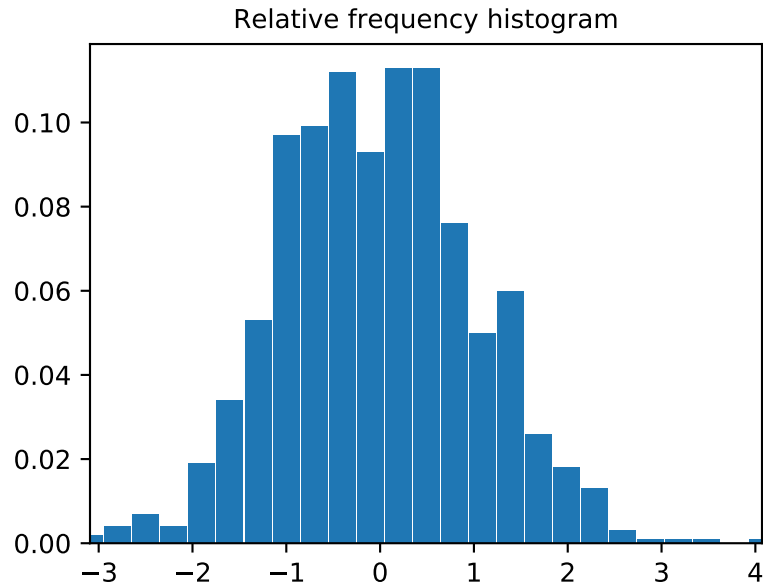

Calculate space of values for x

```
>>> x = res.lowerlimit + np.linspace(0, res.binsize*res.frequency.size,
... res.frequency.size)
```

Plot relative frequency histogram

```
>>> fig = plt.figure(figsize=(5, 4))
>>> ax = fig.add_subplot(1, 1, 1)
>>> ax.bar(x, res.frequency, width=res.binsize)
>>> ax.set_title('Relative frequency histogram')
>>> ax.set_xlim([x.min(), x.max()])
```

```
>>> plt.show()
```

<code>binned_statistic(x, values[, statistic, ...])</code>	Compute a binned statistic for one or more sets of data.
<code>binned_statistic_2d(x, y, values[, ...])</code>	Compute a bidimensional binned statistic for one or more sets of data.
<code>binned_statistic_dd(sample, values[, ...])</code>	Compute a multidimensional binned statistic for a set of data.

### scipy.stats.binned\_statistic

`scipy.stats.binned_statistic(x, values, statistic='mean', bins=10, range=None)`

Compute a binned statistic for one or more sets of data.

This is a generalization of a histogram function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values (or set of values) within each bin.

#### Parameters

**x** [(N,) array\_like] A sequence of values to be binned.

<b>values</b>	[(N,) array_like or list of (N,) array_like] The data on which the statistic will be computed. This must be the same shape as <i>x</i> , or a set of sequences - each the same shape as <i>x</i> . If <i>values</i> is a set of sequences, the statistic will be computed on each independently.
<b>statistic</b>	[string or callable, optional] The statistic to compute (default is 'mean'). The following statistics are available: <ul style="list-style-type: none"> <li>• 'mean': compute the mean of values for points within each bin. Empty bins will be represented by NaN.</li> <li>• 'std': compute the standard deviation within each bin. This is implicitly calculated with <code>ddof=0</code>.</li> <li>• 'median': compute the median of values for points within each bin. Empty bins will be represented by NaN.</li> <li>• 'count': compute the count of points within each bin. This is identical to an unweighted histogram. <i>values</i> array is not referenced.</li> <li>• 'sum': compute the sum of values for points within each bin. This is identical to a weighted histogram.</li> <li>• 'min': compute the minimum of values for points within each bin. Empty bins will be represented by NaN.</li> <li>• 'max': compute the maximum of values for point within each bin. Empty bins will be represented by NaN.</li> <li>• function: a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by <code>function([])</code>, or NaN if this returns an error.</li> </ul>
<b>bins</b>	[int or sequence of scalars, optional] If <i>bins</i> is an int, it defines the number of equal-width bins in the given range (10 by default). If <i>bins</i> is a sequence, it defines the bin edges, including the rightmost edge, allowing for non-uniform bin widths. Values in <i>x</i> that are smaller than lowest bin edge are assigned to bin number 0, values beyond the highest bin are assigned to <code>bins[-1]</code> . If the bin edges are specified, the number of bins will be, $(n_x = \text{len}(\text{bins}) - 1)$ .
<b>range</b>	[(float, float) or [(float, float)], optional] The lower and upper range of the bins. If not provided, range is simply $(x.\text{min}(), x.\text{max}())$ . Values outside the range are ignored.

**Returns**

<b>statistic</b>	[array] The values of the selected statistic in each bin.
<b>bin_edges</b>	[array of dtype float] Return the bin edges $(\text{length}(\text{statistic}) + 1)$ .
<b>binnumber: 1-D ndarray of ints</b>	Indices of the bins (corresponding to <i>bin_edges</i> ) in which each value of <i>x</i> belongs. Same length as <i>values</i> . A binnumber of <i>i</i> means the corresponding value is between $(\text{bin\_edges}[i - 1], \text{bin\_edges}[i])$ .

**See also:**

`numpy.digitize`, `numpy.histogram`, `binned_statistic_2d`, `binned_statistic_dd`

**Notes**

All but the last (righthand-most) bin is half-open. In other words, if *bins* is `[1, 2, 3, 4]`, then the first bin is `[1, 2)` (including 1, but excluding 2) and the second `[2, 3)`. The last bin, however, is `[3, 4]`, which includes 4.

New in version 0.11.0.

## Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

First some basic examples:

Create two evenly spaced bins in the range of the given sample, and sum the corresponding values in each of those bins:

```
>>> values = [1.0, 1.0, 2.0, 1.5, 3.0]
>>> stats.binned_statistic([1, 1, 2, 5, 7], values, 'sum', bins=2)
(array([4. , 4.5]), array([1., 4., 7.]), array([1, 1, 1, 2, 2]))
```

Multiple arrays of values can also be passed. The statistic is calculated on each set independently:

```
>>> values = [[1.0, 1.0, 2.0, 1.5, 3.0], [2.0, 2.0, 4.0, 3.0, 6.0]]
>>> stats.binned_statistic([1, 1, 2, 5, 7], values, 'sum', bins=2)
(array([[4. , 4.5], [8. , 9.]]), array([1., 4., 7.]),
 array([1, 1, 1, 2, 2]))
```

```
>>> stats.binned_statistic([1, 2, 1, 2, 4], np.arange(5), statistic='mean',
↳',
... bins=3)
(array([1., 2., 4.]), array([1., 2., 3., 4.]),
 array([1, 2, 1, 2, 3]))
```

As a second example, we now generate some random data of sailing boat speed as a function of wind speed, and then determine how fast our boat is for certain wind speeds:

```
>>> windspeed = 8 * np.random.rand(500)
>>> boatspeed = .3 * windspeed**.5 + .2 * np.random.rand(500)
>>> bin_means, bin_edges, binnumber = stats.binned_statistic(windspeed,
... boatspeed, statistic='median', bins=[1,2,3,4,5,6,7])
>>> plt.figure()
>>> plt.plot(windspeed, boatspeed, 'b.', label='raw data')
>>> plt.hlines(bin_means, bin_edges[:-1], bin_edges[1:], colors='g', lw=5,
... label='binned statistic of data')
>>> plt.legend()
```

Now we can use `binnumber` to select all datapoints with a windspeed below 1:

```
>>> low_boatspeed = boatspeed[binnumber == 0]
```

As a final example, we will use `bin_edges` and `binnumber` to make a plot of a distribution that shows the mean and distribution around that mean per bin, on top of a regular histogram and the probability distribution function:

```
>>> x = np.linspace(0, 5, num=500)
>>> x_pdf = stats.maxwell.pdf(x)
>>> samples = stats.maxwell.rvs(size=10000)
```

```
>>> bin_means, bin_edges, binnumber = stats.binned_statistic(x, x_pdf,
... statistic='mean', bins=25)
```

(continues on next page)

(continued from previous page)

```
>>> bin_width = (bin_edges[1] - bin_edges[0])
>>> bin_centers = bin_edges[1:] - bin_width/2
```

```
>>> plt.figure()
>>> plt.hist(samples, bins=50, density=True, histtype='stepfilled',
... alpha=0.2, label='histogram of data')
>>> plt.plot(x, x_pdf, 'r-', label='analytical pdf')
>>> plt.hlines(bin_means, bin_edges[:-1], bin_edges[1:], colors='g', lw=2,
... label='binned statistic of data')
>>> plt.plot((binnumber - 0.5) * bin_width, x_pdf, 'g.', alpha=0.5)
>>> plt.legend(fontsize=10)
>>> plt.show()
```

**scipy.stats.binned\_statistic\_2d**

`scipy.stats.binned_statistic_2d(x, y, values, statistic='mean', bins=10, range=None, expand_binnumbers=False)`

Compute a bidimensional binned statistic for one or more sets of data.

This is a generalization of a `histogram2d` function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values (or set of values) within each bin.

**Parameters**

- x** [(N,) array\_like] A sequence of values to be binned along the first dimension.
- y** [(N,) array\_like] A sequence of values to be binned along the second dimension.
- values** [(N,) array\_like or list of (N,) array\_like] The data on which the statistic will be computed. This must be the same shape as *x*, or a list of sequences - each with the same shape as *x*. If *values* is such a list, the statistic will be computed on each independently.
- statistic** [string or callable, optional] The statistic to compute (default is 'mean'). The following statistics are available:
- 'mean': compute the mean of values for points within each bin. Empty bins will be represented by NaN.
  - 'std': compute the standard deviation within each bin. This is implicitly calculated with `ddof=0`.
  - 'median': compute the median of values for points within each bin. Empty bins will be represented by NaN.
  - 'count': compute the count of points within each bin. This is identical to an unweighted histogram. *values* array is not referenced.
  - 'sum': compute the sum of values for points within each bin. This is identical to a weighted histogram.
  - 'min': compute the minimum of values for points within each bin. Empty bins will be represented by NaN.
  - 'max': compute the maximum of values for point within each bin. Empty bins will be represented by NaN.
  - function: a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by `function([])`, or NaN if this returns an error.
- bins** [int or [int, int] or array\_like or [array, array], optional] The bin specification:
- the number of bins for the two dimensions (`nx = ny = bins`),
  - the number of bins in each dimension (`nx, ny = bins`),
  - the bin edges for the two dimensions (`x_edge = y_edge = bins`),
  - the bin edges in each dimension (`x_edge, y_edge = bins`).
- If the bin edges are specified, the number of bins will be, (`nx = len(x_edge)-1`, `ny = len(y_edge)-1`).
- range** [(2,2) array\_like, optional] The leftmost and rightmost edges of the bins along each dimension (if not specified explicitly in the *bins* parameters): `[[xmin, xmax], [ymin, ymax]]`. All values outside of this range will be considered outliers and not tallied in the histogram.
- expand\_binnumbers** [bool, optional] 'False' (default): the returned *binnumber* is a shape (N,) array of linearized bin indices. 'True': the returned *binnumber* is 'unraveled' into a shape (2,N) ndarray, where each row gives the bin numbers in the corresponding dimension. See the *binnumber* returned value, and the *Examples* section.
- New in version 0.17.0.

**Returns**

- statistic** [(nx, ny) ndarray] The values of the selected statistic in each two-dimensional bin.

**x\_edge** [(nx + 1) ndarray] The bin edges along the first dimension.  
**y\_edge** [(ny + 1) ndarray] The bin edges along the second dimension.  
**binnumber** [(N,) array of ints or (2,N) ndarray of ints] This assigns to each element of *sample* an integer that represents the bin in which this observation falls. The representation depends on the *expand\_binnumbers* argument. See *Notes* for details.

**See also:**

`numpy.digitize`, `numpy.histogram2d`, `binned_statistic`, `binned_statistic_dd`

**Notes**

**Binedges:** All but the last (righthand-most) bin is half-open. In other words, if *bins* is [1, 2, 3, 4], then the first bin is [1, 2) (including 1, but excluding 2) and the second [2, 3). The last bin, however, is [3, 4], which *includes* 4.

**binnumber:** This returned argument assigns to each element of *sample* an integer that represents the bin in which it belongs. The representation depends on the *expand\_binnumbers* argument. If 'False' (default): The returned *binnumber* is a shape (N,) array of linearized indices mapping each element of *sample* to its corresponding bin (using row-major ordering). If 'True': The returned *binnumber* is a shape (2,N) ndarray where each row indicates bin placements for each dimension respectively. In each dimension, a binnumber of *i* means the corresponding value is between (D\_edge[i-1], D\_edge[i]), where 'D' is either 'x' or 'y'.

New in version 0.11.0.

**Examples**

```
>>> from scipy import stats
```

Calculate the counts with explicit bin-edges:

```
>>> x = [0.1, 0.1, 0.1, 0.6]
>>> y = [2.1, 2.6, 2.1, 2.1]
>>> binx = [0.0, 0.5, 1.0]
>>> biny = [2.0, 2.5, 3.0]
>>> ret = stats.binned_statistic_2d(x, y, None, 'count', bins=[binx,biny])
>>> ret.statistic
array([[2., 1.],
 [1., 0.]])
```

The bin in which each sample is placed is given by the *binnumber* returned parameter. By default, these are the linearized bin indices:

```
>>> ret.binnumber
array([5, 6, 5, 9])
```

The bin indices can also be expanded into separate entries for each dimension using the *expand\_binnumbers* parameter:

```
>>> ret = stats.binned_statistic_2d(x, y, None, 'count', bins=[binx,biny],
... expand_binnumbers=True)
>>> ret.binnumber
```

(continues on next page)

(continued from previous page)

```
array([[1, 1, 1, 2],
 [1, 2, 1, 1]])
```

Which shows that the first three elements belong in the xbin 1, and the fourth into xbin 2; and so on for y.

### scipy.stats.binned\_statistic\_dd

`scipy.stats.binned_statistic_dd`(*sample*, *values*, *statistic='mean'*, *bins=10*, *range=None*, *expand\_binnumbers=False*)

Compute a multidimensional binned statistic for a set of data.

This is a generalization of a `histogramdd` function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values within each bin.

#### Parameters

- |                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>sample</b>            | [array_like] Data to histogram passed as a sequence of D arrays of length N, or as an (N,D) array.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>values</b>            | [(N,) array_like or list of (N,) array_like] The data on which the statistic will be computed. This must be the same shape as <i>sample</i> , or a list of sequences - each with the same shape as <i>sample</i> . If <i>values</i> is such a list, the statistic will be computed on each independently.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>statistic</b>         | [string or callable, optional] The statistic to compute (default is 'mean'). The following statistics are available: <ul style="list-style-type: none"> <li>• 'mean' : compute the mean of values for points within each bin. Empty bins will be represented by NaN.</li> <li>• 'median' : compute the median of values for points within each bin. Empty bins will be represented by NaN.</li> <li>• 'count' : compute the count of points within each bin. This is identical to an unweighted histogram. <i>values</i> array is not referenced.</li> <li>• 'sum' : compute the sum of values for points within each bin. This is identical to a weighted histogram.</li> <li>• 'std' : compute the standard deviation within each bin. This is implicitly calculated with <code>ddof=0</code>.</li> <li>• 'min' : compute the minimum of values for points within each bin. Empty bins will be represented by NaN.</li> <li>• 'max' : compute the maximum of values for point within each bin. Empty bins will be represented by NaN.</li> <li>• function : a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by <code>function([])</code>, or NaN if this returns an error.</li> </ul> |
| <b>bins</b>              | [sequence or int, optional] The bin specification must be in one of the following forms: <ul style="list-style-type: none"> <li>• A sequence of arrays describing the bin edges along each dimension.</li> <li>• The number of bins for each dimension (<code>nx, ny, ... = bins</code>).</li> <li>• The number of bins for all dimensions (<code>nx = ny = ... = bins</code>).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>range</b>             | [sequence, optional] A sequence of lower and upper bin edges to be used if the edges are not given explicitly in <i>bins</i> . Defaults to the minimum and maximum values along each dimension.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>expand_binnumbers</b> | [bool, optional] 'False' (default): the returned <i>binnumber</i> is a shape (N,) array of linearized bin indices. 'True': the returned <i>binnumber</i> is 'unraveled' into a shape (D,N) ndarray, where each row gives the bin numbers in the corresponding dimension. See the <i>binnumber</i> returned value, and the <i>Examples</i> section of <code>binned_statistic_2d</code> .<br>New in version 0.17.0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Returns**

- statistic** [ndarray, shape(nx1, nx2, nx3,...)] The values of the selected statistic in each two-dimensional bin.
- bin\_edges** [list of ndarrays] A list of D arrays describing the (nxi + 1) bin edges for each dimension.
- binnumber** [(N,) array of ints or (D,N) ndarray of ints] This assigns to each element of *sample* an integer that represents the bin in which this observation falls. The representation depends on the *expand\_binnumbers* argument. See *Notes* for details.

**See also:**

`numpy.digitize`, `numpy.histogramdd`, `binned_statistic`, `binned_statistic_2d`

**Notes**

**Binedges:** All but the last (righthand-most) bin is half-open in each dimension. In other words, if *bins* is [1, 2, 3, 4], then the first bin is [1, 2) (including 1, but excluding 2) and the second [2, 3). The last bin, however, is [3, 4], which *includes* 4.

**binnumber:** This returned argument assigns to each element of *sample* an integer that represents the bin in which it belongs. The representation depends on the *expand\_binnumbers* argument. If 'False' (default): The returned *binnumber* is a shape (N,) array of linearized indices mapping each element of *sample* to its corresponding bin (using row-major ordering). If 'True': The returned *binnumber* is a shape (D,N) ndarray where each row indicates bin placements for each dimension respectively. In each dimension, a binnumber of *i* means the corresponding value is between (bin\_edges[D][i-1], bin\_edges[D][i]), for each dimension 'D'.

New in version 0.11.0.

## 6.28.9 Correlation functions

<code>f_oneway(*args)</code>	Performs a 1-way ANOVA.
<code>pearsonr(x, y)</code>	Pearson correlation coefficient and p-value for testing non-correlation.
<code>spearmanr(a[, b, axis, nan_policy])</code>	Calculate a Spearman rank-order correlation coefficient and the p-value to test for non-correlation.
<code>pointbiserialr(x, y)</code>	Calculate a point biserial correlation coefficient and its p-value.
<code>kendalltau(x, y[, initial_lexsort, ...])</code>	Calculate Kendall's tau, a correlation measure for ordinal data.
<code>weightedtau(x, y[, rank, weigher, additive])</code>	Compute a weighted version of Kendall's $\tau$ .
<code>linregress(x[, y])</code>	Calculate a linear least-squares regression for two sets of measurements.
<code>siegelslopes(y[, x, method])</code>	Computes the Siegel estimator for a set of points (x, y).
<code>theilslopes(y[, x, alpha])</code>	Computes the Theil-Sen estimator for a set of points (x, y).

### scipy.stats.f\_oneway

`scipy.stats.f_oneway(*args)`

Performs a 1-way ANOVA.

The one-way ANOVA tests the null hypothesis that two or more groups have the same population mean. The test is applied to samples from two or more groups, possibly with differing sizes.

**Parameters**

**sample1, sample2, ...**  
 [array\_like] The sample measurements for each group.

**Returns**

**statistic** [float] The computed F-value of the test.  
**pvalue** [float] The associated p-value from the F-distribution.

**Notes**

The ANOVA test has important assumptions that must be satisfied in order for the associated p-value to be valid.

1. The samples are independent.
2. Each sample is from a normally distributed population.
3. The population standard deviations of the groups are all equal. This property is known as homoscedasticity.

If these assumptions are not true for a given set of data, it may still be possible to use the Kruskal-Wallis H-test (*scipy.stats.kruskal*) although with some loss of power.

The algorithm is from Heiman[2], pp.394-7.

```

**scipy.stats.pearsonr**

`scipy.stats.pearsonr(x, y)`

Pearson correlation coefficient and p-value for testing non-correlation.

The Pearson correlation coefficient [1] measures the linear relationship between two datasets. The calculation of the p-value relies on the assumption that each dataset is normally distributed. (See Kowalski [3] for a discussion of the effects of non-normality of the input on the distribution of the correlation coefficient.) Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact linear relationship. Positive correlations imply that as  $x$  increases, so does  $y$ . Negative correlations imply that as  $x$  increases,  $y$  decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Pearson correlation at least as extreme as the one computed from these datasets.

**Parameters**

**x** [(N,) array\_like] Input  
**y** [(N,) array\_like] Input

**Returns**

**r** [float] Pearson’s correlation coefficient  
**p-value** [float] two-tailed p-value

**Warns**

**PearsonRConstantInputWarning**

Raised if an input is a constant array. The correlation coefficient is not defined in this case, so `np.nan` is returned.

**PearsonRNearConstantInputWarning**

Raised if an input is “nearly” constant. The array  $x$  is considered nearly constant if `norm(x - mean(x)) < 1e-13 * abs(mean(x))`. Numerical errors in the calculation `x - mean(x)` in this case might result in an inaccurate calculation of  $r$ .

See also:

[spearmanr](#)

Spearman rank-order correlation coefficient.

[kendalltau](#)

Kendall’s tau, a correlation measure for ordinal data.

**Notes**

The correlation coefficient is calculated as follows:

$$r = \frac{\sum(x - m_x)(y - m_y)}{\sqrt{\sum(x - m_x)^2 \sum(y - m_y)^2}}$$

where  $m_x$  is the mean of the vector  $x$  and  $m_y$  is the mean of the vector  $y$ .

Under the assumption that  $x$  and  $y$  are drawn from independent normal distributions (so the population correlation coefficient is 0), the probability density function of the sample correlation coefficient  $r$  is ([1], [2]):

$$f(r) = \frac{(1 - r^2)^{(n/2 - 2)}}{B(1/2, n/2 - 1)}$$

where  $n$  is the number of samples, and  $B$  is the beta function. This is sometimes referred to as the exact distribution of  $r$ . This is the distribution that is used in `pearsonr` to compute the p-value. The distribution is a beta distribution on the interval  $[-1, 1]$ , with equal shape parameters  $a = b = n/2 - 1$ . In terms of SciPy’s implementation of the beta distribution, the distribution of  $r$  is:

```
dist = scipy.stats.beta(n/2 - 1, n/2 - 1, loc=-1, scale=2)
```

The p-value returned by `pearsonr` is a two-sided p-value. For a given sample with correlation coefficient  $r$ , the p-value is the probability that  $\text{abs}(r')$  of a random sample  $x'$  and  $y'$  drawn from the population with zero correlation would be greater than or equal to  $\text{abs}(r)$ . In terms of the object `dist` shown above, the p-value for a given  $r$  and length  $n$  can be computed as:

```
p = 2*dist.cdf(-abs(r))
```

When  $n$  is 2, the above continuous distribution is not well-defined. One can interpret the limit of the beta distribution as the shape parameters  $a$  and  $b$  approach  $a = b = 0$  as a discrete distribution with equal probability masses at  $r = 1$  and  $r = -1$ . More directly, one can observe that, given the data  $x = [x_1, x_2]$  and  $y = [y_1, y_2]$ , and assuming  $x_1 \neq x_2$  and  $y_1 \neq y_2$ , the only possible values for  $r$  are 1 and -1. Because  $\text{abs}(r')$  for any sample  $x'$  and  $y'$  with length 2 will be 1, the two-sided p-value for a sample of length 2 is always 1.

```

## scipy.stats.spearmanr

`scipy.stats.spearmanr` ( $a, b=None, axis=0, nan_policy='propagate'$ )

Calculate a Spearman rank-order correlation coefficient and the p-value to test for non-correlation.

The Spearman correlation is a nonparametric measure of the monotonicity of the relationship between two datasets. Unlike the Pearson correlation, the Spearman correlation does not assume that both datasets are normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact monotonic relationship. Positive correlations imply that as  $x$  increases, so does  $y$ . Negative correlations imply that as  $x$  increases,  $y$  decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Spearman correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

### Parameters

**a, b** [1D or 2D array\_like, b is optional] One or two 1-D or 2-D arrays containing multiple variables and observations. When these are 1-D, each represents a vector of observations of a single variable. For the behavior in the 2-D case, see under `axis`, below. Both arrays need to have the same length in the `axis` dimension.

**axis** [int or None, optional] If axis=0 (default), then each column represents a variable, with observations in the rows. If axis=1, the relationship is transposed: each row represents a variable, while the columns contain observations. If axis=None, then both arrays will be raveled.

**nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

**correlation** [float or ndarray (2-D square)] Spearman correlation matrix or correlation coefficient (if only 2 variables are given as parameters. Correlation matrix is square with length equal to total number of variables (columns or rows) in a and b combined.

**pvalue** [float] The two-sided p-value for a hypothesis test whose null hypothesis is that two sets of data are uncorrelated, has same dimension as rho.

## scipy.stats.pointbiserialr

`scipy.stats.pointbiserialr(x, y)`

Calculate a point biserial correlation coefficient and its p-value.

The point biserial correlation is used to measure the relationship between a binary variable,  $x$ , and a continuous variable,  $y$ . Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply a determinative relationship.

This function uses a shortcut formula but produces the same result as `pearsonr`.

### Parameters

**x** [array\_like of bools] Input array.  
**y** [array\_like] Input array.

### Returns

**correlation** [float] R value  
**pvalue** [float] 2-tailed p-value

## Notes

`pointbiserialr` uses a t-test with  $n-1$  degrees of freedom. It is equivalent to `pearsonr`.

The value of the point-biserial correlation can be calculated from:

$$r_{pb} = \frac{\bar{Y}_1 - \bar{Y}_0}{s_y} \sqrt{\frac{N_1 N_2}{N(N-1)}}$$

Where  $Y_0$  and  $Y_1$  are means of the metric observations coded 0 and 1 respectively;  $N_0$  and  $N_1$  are number of observations coded 0 and 1 respectively;  $N$  is the total number of observations and  $s_y$  is the standard deviation of all the metric observations.

A value of  $r_{pb}$  that is significantly different from zero is completely equivalent to a significant difference in means between the two groups. Thus, an independent groups t Test with  $N - 2$  degrees of freedom may be used to test whether  $r_{pb}$  is nonzero. The relation between the t-statistic for comparing two independent groups and  $r_{pb}$  is given by:

$$t = \sqrt{N-2} \frac{r_{pb}}{\sqrt{1-r_{pb}^2}}$$

 [0.8660254, 1.]])
```

## scipy.stats.kendalltau

`scipy.stats.kendalltau(x, y, initial_lexsort=None, nan_policy='propagate', method='auto')`

Calculate Kendall's tau, a correlation measure for ordinal data.

Kendall's tau is a measure of the correspondence between two rankings. Values close to 1 indicate strong agreement, values close to -1 indicate strong disagreement. This is the 1945 “tau-b” version of Kendall's tau [2], which can account for ties and which reduces to the 1938 “tau-a” version [1] in absence of ties.

### Parameters

**x, y** [array\_like] Arrays of rankings, of the same shape. If arrays are not 1-D, they will be flattened to 1-D.

**initial\_lexsort**

[bool, optional] Unused (deprecated).

**nan\_policy**

[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'. Note that if the input contains nan 'omit' delegates to `mstats_basic.kendalltau()`, which has a different implementation.

**method: {'auto', 'asymptotic', 'exact'}, optional**

Defines which method is used to calculate the p-value [5]. 'asymptotic' uses a normal approximation valid for large samples. 'exact' computes the exact p-value, but can only be used if no ties are present. 'auto' is the default and selects the appropriate method based on a trade-off between speed and accuracy.

### Returns

**correlation**

[float] The tau statistic.

**pvalue**

[float] The two-sided p-value for a hypothesis test whose null hypothesis is an absence of association,  $\tau = 0$ .

See also:

### spearmanr

Calculates a Spearman rank-order correlation coefficient.

### theilslopes

Computes the Theil-Sen estimator for a set of points (x, y).

## weightedtau

Computes a weighted version of Kendall's tau.

### Notes

The definition of Kendall's tau that is used is [2]:

$$\tau = (P - Q) / \sqrt{((P + Q + T) * (P + Q + U))}$$

where P is the number of concordant pairs, Q the number of discordant pairs, T the number of ties only in  $x$ , and U the number of ties only in  $y$ . If a tie occurs for the same pair in both  $x$  and  $y$ , it is not added to either T or U.

```
>>> from scipy import stats
>>> x1 = [12, 2, 1, 12, 2]
>>> x2 = [1, 4, 7, 1, 0]
>>> tau, p_value = stats.kendalltau(x1, x2)
>>> tau
-0.47140452079103173
>>> p_value
0.2827454599327748
```

## scipy.stats.weightedtau

`scipy.stats.weightedtau(x, y, rank=True, weigher=None, additive=True)`

Compute a weighted version of Kendall's  $\tau$ .

The weighted  $\tau$  is a weighted version of Kendall's  $\tau$  in which exchanges of high weight are more influential than exchanges of low weight. The default parameters compute the additive hyperbolic version of the index,  $\tau_h$ , which has been shown to provide the best balance between important and unimportant elements [1].

The weighting is defined by means of a rank array, which assigns a nonnegative rank to each element, and a weigher function, which assigns a weight based from the rank to each element. The weight of an exchange is then the sum or the product of the weights of the ranks of the exchanged elements. The default parameters compute  $\tau_h$ : an exchange between elements with rank  $r$  and  $s$  (starting from zero) has weight  $1/(r + 1) + 1/(s + 1)$ .

Specifying a rank array is meaningful only if you have in mind an external criterion of importance. If, as it usually happens, you do not have in mind a specific rank, the weighted  $\tau$  is defined by averaging the values obtained using the decreasing lexicographical rank by  $(x, y)$  and by  $(y, x)$ . This is the behavior with default parameters.

Note that if you are computing the weighted  $\tau$  on arrays of ranks, rather than of scores (i.e., a larger value implies a lower rank) you must negate the ranks, so that elements of higher rank are associated with a larger value.

#### Parameters

**x, y** [array\_like] Arrays of scores, of the same shape. If arrays are not 1-D, they will be flattened to 1-D.

**rank: array\_like of ints or bool, optional**

A nonnegative rank assigned to each element. If it is None, the decreasing lexicographical rank by  $(x, y)$  will be used: elements of higher rank will be those with larger  $x$ -values, using  $y$ -values to break ties (in particular, swapping  $x$  and  $y$  will give a different result). If it is False, the element indices will be used directly as ranks. The default is True, in which case this function returns the average of the values obtained using the decreasing lexicographical rank by  $(x, y)$  and by  $(y, x)$ .

**weigher** [callable, optional] The weigher function. Must map nonnegative integers (zero representing the most important element) to a nonnegative weight. The default, None, provides hyperbolic weighing, that is, rank  $r$  is mapped to weight  $1/(r + 1)$ .

**additive** [bool, optional] If True, the weight of an exchange is computed by adding the weights of the ranks of the exchanged elements; otherwise, the weights are multiplied. The default is True.

**Returns****correlation**

[float] The weighted  $\tau$  correlation index.

**pvalue** [float] Presently `np.nan`, as the null statistics is unknown (even in the additive hyperbolic case).

**See also:****kendalltau**

Calculates Kendall's tau.

**spearmanr**

Calculates a Spearman rank-order correlation coefficient.

**theilslopes**

Computes the Theil-Sen estimator for a set of points  $(x, y)$ .

**Notes**

This function uses an  $O(n \log n)$ , mergesort-based algorithm [1] that is a weighted extension of Knight's algorithm for Kendall's  $\tau$  [2]. It can compute Shieh's weighted  $\tau$  [3] between rankings without ties (i.e., permutations) by setting *additive* and *rank* to False, as the definition given in [1] is a generalization of Shieh's.

NaNs are considered the smallest possible score.

New in version 0.19.0.

**References**

**Examples**

```
>>> from scipy import stats
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
>>> tau, p_value = stats.weightedtau(x, y)
>>> tau
```

(continues on next page)

(continued from previous page)

```
-0.56694968153682723
>>> p_value
nan
>>> tau, p_value = stats.weightedtau(x, y, additive=False)
>>> tau
-0.62205716951801038
```

NaNs are considered the smallest possible score:

```
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, np.nan]
>>> tau, _ = stats.weightedtau(x, y)
>>> tau
-0.56694968153682723
```

This is exactly Kendall's tau:

```
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
>>> tau, _ = stats.weightedtau(x, y, weigher=lambda x: 1)
>>> tau
-0.47140452079103173
```

```
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
>>> stats.weightedtau(x, y, rank=None)
WeightedTauResult(correlation=-0.4157652301037516, pvalue=nan)
>>> stats.weightedtau(y, x, rank=None)
WeightedTauResult(correlation=-0.7181341329699028, pvalue=nan)
```

## scipy.stats.linregress

`scipy.stats.linregress(x, y=None)`

Calculate a linear least-squares regression for two sets of measurements.

### Parameters

**x, y** [array\_like] Two sets of measurements. Both arrays should have the same length. If only *x* is given (and *y=None*), then it must be a two-dimensional array where one dimension has length 2. The two sets of measurements are then found by splitting the array along the length-2 dimension. In the case where *y=None* and *x* is a 2x2 array, `linregress(x)` is equivalent to `linregress(x[0], x[1])`.

### Returns

**slope** [float] Slope of the regression line.  
**intercept** [float] Intercept of the regression line.  
**rvalue** [float] Correlation coefficient.  
**pvalue** [float] Two-sided p-value for a hypothesis test whose null hypothesis is that the slope is zero, using Wald Test with t-distribution of the test statistic.  
**stderr** [float] Standard error of the estimated gradient.

See also:

**scipy.optimize.curve\_fit**

Use non-linear least squares to fit a function to data.

**scipy.optimize.leastsq**

Minimize the sum of squares of a set of equations.

**Notes**

Missing values are considered pair-wise: if a value is missing in  $x$ , the corresponding value in  $y$  is masked.

**Examples**

```
>>> import matplotlib.pyplot as plt
>>> from scipy import stats
```

Generate some data:

```
>>> np.random.seed(12345678)
>>> x = np.random.random(10)
>>> y = 1.6*x + np.random.random(10)
```

Perform the linear regression:

```
>>> slope, intercept, r_value, p_value, std_err = stats.linregress(x, y)
>>> print("slope: %f intercept: %f" % (slope, intercept))
slope: 1.944864 intercept: 0.268578
```

To get coefficient of determination (R-squared):

```
>>> print("R-squared: %f" % r_value**2)
R-squared: 0.735498
```

Plot the data along with the fitted line:

```
>>> plt.plot(x, y, 'o', label='original data')
>>> plt.plot(x, intercept + slope*x, 'r', label='fitted line')
>>> plt.legend()
>>> plt.show()
```

Example for the case where only  $x$  is provided as a 2x2 array:

```
>>> x = np.array([[0, 1], [0, 2]])
>>> r = stats.linregress(x)
>>> r.slope, r.intercept
(2.0, 0.0)
```

**scipy.stats.siegelslopes**

`scipy.stats.siegelslopes` ( $y$ ,  $x=None$ ,  $method='hierarchical'$ )

Computes the Siegel estimator for a set of points  $(x, y)$ .

`siegelslopes` implements a method for robust linear regression using repeated medians (see [1]) to fit a line to the points  $(x, y)$ . The method is robust to outliers with an asymptotic breakdown point of 50%.

#### Parameters

- y** [array\_like] Dependent variable.
- x** [array\_like or None, optional] Independent variable. If None, use `arange(len(y))` instead.
- method** [{"hierarchical", "separate"}] If 'hierarchical', estimate the intercept using the estimated slope `medslope` (default option). If 'separate', estimate the intercept independent of the estimated slope. See Notes for details.

#### Returns

- medslope** [float] Estimate of the slope of the regression line.
- medintercept** [float] Estimate of the intercept of the regression line.

See also:

#### `theilslopes`

a similar technique without repeated medians

#### Notes

With  $n = \text{len}(y)$ , compute  $m_j$  as the median of the slopes from the point  $(x[j], y[j])$  to all other  $n-1$  points. `medslope` is then the median of all slopes  $m_j$ . Two ways are given to estimate the intercept in [1] which can be chosen via the parameter `method`. The hierarchical approach uses the estimated slope `medslope` and computes `medintercept` as the median of  $y - \text{medslope} * x$ . The other approach estimates the intercept separately as follows: for each point  $(x[j], y[j])$ , compute the intercepts of all the  $n-1$  lines through the remaining points and take the median  $i_j$ . `medintercept` is the median of the  $i_j$ .

The implementation computes  $n$  times the median of a vector of size  $n$  which can be slow for large vectors. There are more efficient algorithms (see [2]) which are not implemented here.

## References

[1], [2]

## Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

```
>>> x = np.linspace(-5, 5, num=150)
>>> y = x + np.random.normal(size=x.size)
>>> y[11:15] += 10 # add outliers
>>> y[-5:] -= 7
```

Compute the slope and intercept. For comparison, also compute the least-squares fit with `linregress`:

```
>>> res = stats.siegel slopes(y, x)
>>> lsq_res = stats.linregress(x, y)
```

Plot the results. The Siegel regression line is shown in red. The green line shows the least-squares fit for comparison.

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, y, 'b.')
>>> ax.plot(x, res[1] + res[0] * x, 'r-')
>>> ax.plot(x, lsq_res[1] + lsq_res[0] * x, 'g-')
>>> plt.show()
```

**scipy.stats.theilslopes**

`scipy.stats.theilslopes` (*y*, *x=None*, *alpha=0.95*)  
 Computes the Theil-Sen estimator for a set of points (*x*, *y*).

`theilslopes` implements a method for robust linear regression. It computes the slope as the median of all slopes between paired values.

#### Parameters

<b>y</b>	[array_like] Dependent variable.
<b>x</b>	[array_like or None, optional] Independent variable. If None, use <code>arange(len(y))</code> instead.
<b>alpha</b>	[float, optional] Confidence degree between 0 and 1. Default is 95% confidence. Note that <i>alpha</i> is symmetric around 0.5, i.e. both 0.1 and 0.9 are interpreted as “find the 90% confidence interval”.

#### Returns

<b>medslope</b>	[float] Theil slope.
<b>medintercept</b>	[float] Intercept of the Theil line, as $\text{median}(y) - \text{medslope} * \text{median}(x)$ .
<b>lo_slope</b>	[float] Lower bound of the confidence interval on <i>medslope</i> .
<b>up_slope</b>	[float] Upper bound of the confidence interval on <i>medslope</i> .

See also:

#### `siegelslopes`

a similar technique using repeated medians

#### Notes

The implementation of `theilslopes` follows [1]. The intercept is not defined in [1], and here it is defined as  $\text{median}(y) - \text{medslope} * \text{median}(x)$ , which is given in [3]. Other definitions of the intercept exist in the literature. A confidence interval for the intercept is not given as this question is not addressed in [1].

#### References

[1], [2], [3]

#### Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

```
>>> x = np.linspace(-5, 5, num=150)
>>> y = x + np.random.normal(size=x.size)
>>> y[11:15] += 10 # add outliers
>>> y[-5:] -= 7
```

Compute the slope, intercept and 90% confidence interval. For comparison, also compute the least-squares fit with `linregress`:

```
>>> res = stats.theilslopes(y, x, 0.90)
>>> lsq_res = stats.linregress(x, y)
```

Plot the results. The Theil-Sen regression line is shown in red, with the dashed red lines illustrating the confidence interval of the slope (note that the dashed red lines are not the confidence interval of the regression as the confidence interval of the intercept is not included). The green line shows the least-squares fit for comparison.

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, y, 'b.')
>>> ax.plot(x, res[1] + res[0] * x, 'r-')
>>> ax.plot(x, res[1] + res[2] * x, 'r--')
>>> ax.plot(x, res[1] + res[3] * x, 'r--')
>>> ax.plot(x, lsq_res[1] + lsq_res[0] * x, 'g-')
>>> plt.show()
```

### 6.28.10 Statistical tests

<code>ttest_1samp(a, popmean[, axis, nan_policy])</code>	Calculate the T-test for the mean of ONE group of scores.
<code>ttest_ind(a, b[, axis, equal_var, nan_policy])</code>	Calculate the T-test for the means of <i>two independent</i> samples of scores.
<code>ttest_ind_from_stats(mean1, std1, nobs1, ...)</code>	T-test for means of two independent samples from descriptive statistics.
<code>ttest_rel(a, b[, axis, nan_policy])</code>	Calculate the T-test on TWO RELATED samples of scores, a and b.
<code>kstest(rvs, cdf[, args, N, alternative, mode])</code>	Perform the Kolmogorov-Smirnov test for goodness of fit.
<code>chisquare(f_obs[, f_exp, ddof, axis])</code>	Calculate a one-way chi square test.
<code>power_divergence(f_obs[, f_exp, ddof, axis, ...])</code>	Cressie-Read power divergence statistic and goodness of fit test.
<code>ks_2samp(data1, data2[, alternative, mode])</code>	Compute the Kolmogorov-Smirnov statistic on 2 samples.
<code>epps_singleton_2samp(x, y[, t])</code>	Compute the Epps-Singleton (ES) test statistic.
<code>mannwhitneyu(x, y[, use_continuity, alternative])</code>	Compute the Mann-Whitney rank test on samples x and y.

Continued on next page

Table 259 – continued from previous page

<code>tiecorrect</code> (rankvals)	Tie correction factor for ties in the Mann-Whitney U and Kruskal-Wallis H tests.
<code>rankdata</code> (a[, method])	Assign ranks to data, dealing with ties appropriately.
<code>ranksums</code> (x, y)	Compute the Wilcoxon rank-sum statistic for two samples.
<code>wilcoxon</code> (x[, y, zero_method, correction, ...])	Calculate the Wilcoxon signed-rank test.
<code>kruskal</code> (*args, **kwargs)	Compute the Kruskal-Wallis H-test for independent samples
<code>friedmanchisquare</code> (*args)	Compute the Friedman test for repeated measurements
<code>brunnermunzel</code> (x, y[, alternative, ...])	Computes the Brunner-Munzel test on samples x and y
<code>combine_pvalues</code> (pvalues[, method, weights])	Methods for combining the p-values of independent tests bearing upon the same hypothesis.
<code>jarque_bera</code> (x)	Perform the Jarque-Bera goodness of fit test on sample data.

### scipy.stats.ttest\_1samp

`scipy.stats.ttest_1samp` (*a*, *popmean*, *axis=0*, *nan\_policy='propagate'*)

Calculate the T-test for the mean of ONE group of scores.

This is a two-sided test for the null hypothesis that the expected value (mean) of a sample of independent observations *a* is equal to the given population mean, *popmean*.

#### Parameters

- a** [array\_like] sample observation
- popmean** [float or array\_like] expected value in null hypothesis. If array\_like, then it must have the same shape as *a* excluding the axis dimension
- axis** [int or None, optional] Axis along which to compute test. If None, compute over the whole array *a*.
- nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

#### Returns

- statistic** [float or array] t-statistic
- pvalue** [float or array] two-tailed p-value

### Examples

```
>>> from scipy import stats
```

```
>>> np.random.seed(7654567) # fix seed to get the same result
>>> rvs = stats.norm.rvs(loc=5, scale=10, size=(50,2))
```

Test if mean of random sample is equal to true mean, and different mean. We reject the null hypothesis in the second case and don't reject it in the first case.

```
>>> stats.ttest_1samp(rvs, 5.0)
(array([-0.68014479, -0.04323899]), array([0.49961383, 0.96568674]))
```

(continues on next page)

(continued from previous page)

```
>>> stats.ttest_1samp(rvs, 0.0)
(array([2.77025808, 4.11038784]), array([0.00789095, 0.00014999]))
```

Examples using axis and non-scalar dimension for population mean.

```
>>> stats.ttest_1samp(rvs, [5.0, 0.0])
(array([-0.68014479, 4.11038784]), array([4.99613833e-01, 1.
→49986458e-04]))
>>> stats.ttest_1samp(rvs.T, [5.0, 0.0], axis=1)
(array([-0.68014479, 4.11038784]), array([4.99613833e-01, 1.
→49986458e-04]))
>>> stats.ttest_1samp(rvs, [[5.0], [0.0]])
(array([[-0.68014479, -0.04323899],
 [2.77025808, 4.11038784]]), array([[4.99613833e-01, 9.
→65686743e-01],
 [7.89094663e-03, 1.49986458e-04]]))
```

## scipy.stats.ttest\_ind

`scipy.stats.ttest_ind(a, b, axis=0, equal_var=True, nan_policy='propagate')`

Calculate the T-test for the means of *two independent* samples of scores.

This is a two-sided test for the null hypothesis that 2 independent samples have identical average (expected) values. This test assumes that the populations have identical variances by default.

### Parameters

- a, b** [array\_like] The arrays must have the same shape, except in the dimension corresponding to *axis* (the first, by default).
- axis** [int or None, optional] Axis along which to compute test. If None, compute over the whole arrays, *a*, and *b*.
- equal\_var** [bool, optional] If True (default), perform a standard independent 2 sample test that assumes equal population variances [1]. If False, perform Welch's t-test, which does not assume equal population variance [2].  
New in version 0.11.0.
- nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

### Returns

- statistic** [float or array] The calculated t-statistic.
- pvalue** [float or array] The two-tailed p-value.

## Notes

We can use this test, if we observe two independent samples from the same or different population, e.g. exam scores of boys and girls or of two ethnic groups. The test measures whether the average (expected) value differs significantly across samples. If we observe a large p-value, for example larger than 0.05 or 0.1, then we cannot reject the null hypothesis of identical average scores. If the p-value is smaller than the threshold, e.g. 1%, 5% or 10%, then we reject the null hypothesis of equal averages.

## References

[1], [2]

## Examples

```
>>> from scipy import stats
>>> np.random.seed(12345678)
```

Test with sample with identical means:

```
>>> rvs1 = stats.norm.rvs(loc=5, scale=10, size=500)
>>> rvs2 = stats.norm.rvs(loc=5, scale=10, size=500)
>>> stats.ttest_ind(rvs1, rvs2)
(0.26833823296239279, 0.78849443369564776)
>>> stats.ttest_ind(rvs1, rvs2, equal_var = False)
(0.26833823296239279, 0.78849452749500748)
```

`ttest_ind` underestimates p for unequal variances:

```
>>> rvs3 = stats.norm.rvs(loc=5, scale=20, size=500)
>>> stats.ttest_ind(rvs1, rvs3)
(-0.46580283298287162, 0.64145827413436174)
>>> stats.ttest_ind(rvs1, rvs3, equal_var = False)
(-0.46580283298287162, 0.64149646246569292)
```

When  $n_1 \neq n_2$ , the equal variance t-statistic is no longer equal to the unequal variance t-statistic:

```
>>> rvs4 = stats.norm.rvs(loc=5, scale=20, size=100)
>>> stats.ttest_ind(rvs1, rvs4)
(-0.99882539442782481, 0.3182832709103896)
>>> stats.ttest_ind(rvs1, rvs4, equal_var = False)
(-0.69712570584654099, 0.48716927725402048)
```

T-test with different means, variance, and n:

```
>>> rvs5 = stats.norm.rvs(loc=8, scale=20, size=100)
>>> stats.ttest_ind(rvs1, rvs5)
(-1.4679669854490653, 0.14263895620529152)
>>> stats.ttest_ind(rvs1, rvs5, equal_var = False)
(-0.94365973617132992, 0.34744170334794122)
```

## scipy.stats.ttest\_ind\_from\_stats

`scipy.stats.ttest_ind_from_stats` (*mean1, std1, nobs1, mean2, std2, nobs2, equal\_var=True*)

T-test for means of two independent samples from descriptive statistics.

This is a two-sided test for the null hypothesis that two independent samples have identical average (expected) values.

### Parameters

**mean1** [array\_like] The mean(s) of sample 1.  
**std1** [array\_like] The standard deviation(s) of sample 1.

**nobs1** [array\_like] The number(s) of observations of sample 1.  
**mean2** [array\_like] The mean(s) of sample 2  
**std2** [array\_like] The standard deviations(s) of sample 2.  
**nobs2** [array\_like] The number(s) of observations of sample 2.  
**equal\_var** [bool, optional] If True (default), perform a standard independent 2 sample test that assumes equal population variances [1]. If False, perform Welch's t-test, which does not assume equal population variance [2].

**Returns**

**statistic** [float or array] The calculated t-statistics  
**pvalue** [float or array] The two-tailed p-value.

**See also:**

`scipy.stats.ttest_ind`

**Notes**

New in version 0.16.0.

**References**

[1], [2]

**Examples**

Suppose we have the summary data for two samples, as follows:

	Size	Sample Mean	Sample Variance
Sample 1	13	15.0	87.5
Sample 2	11	12.0	39.0

Apply the t-test to this data (with the assumption that the population variances are equal):

```
>>> from scipy.stats import ttest_ind_from_stats
>>> ttest_ind_from_stats(mean1=15.0, std1=np.sqrt(87.5), nobs1=13,
... mean2=12.0, std2=np.sqrt(39.0), nobs2=11)
Ttest_indResult(statistic=0.9051358093310269, pvalue=0.3751996797581487)
```

For comparison, here is the data from which those summary statistics were taken. With this data, we can compute the same result using `scipy.stats.ttest_ind`:

```
>>> a = np.array([1, 3, 4, 6, 11, 13, 15, 19, 22, 24, 25, 26, 26])
>>> b = np.array([2, 4, 6, 9, 11, 13, 14, 15, 18, 19, 21])
>>> from scipy.stats import ttest_ind
>>> ttest_ind(a, b)
Ttest_indResult(statistic=0.905135809331027, pvalue=0.3751996797581486)
```

## scipy.stats.ttest\_rel

`scipy.stats.ttest_rel(a, b, axis=0, nan_policy='propagate')`

Calculate the T-test on TWO RELATED samples of scores, a and b.

This is a two-sided test for the null hypothesis that 2 related or repeated samples have identical average (expected) values.

### Parameters

<b>a, b</b>	[array_like] The arrays must have the same shape.
<b>axis</b>	[int or None, optional] Axis along which to compute test. If None, compute over the whole arrays, <i>a</i> , and <i>b</i> .
<b>nan_policy</b>	[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

### Returns

<b>statistic</b>	[float or array] t-statistic
<b>pvalue</b>	[float or array] two-tailed p-value

## Notes

Examples for the use are scores of the same set of student in different exams, or repeated sampling from the same units. The test measures whether the average score differs significantly across samples (e.g. exams). If we observe a large p-value, for example greater than 0.05 or 0.1 then we cannot reject the null hypothesis of identical average scores. If the p-value is smaller than the threshold, e.g. 1%, 5% or 10%, then we reject the null hypothesis of equal averages. Small p-values are associated with large t-statistics.

## References

[https://en.wikipedia.org/wiki/T-test#Dependent\\_t-test\\_for\\_paired\\_samples](https://en.wikipedia.org/wiki/T-test#Dependent_t-test_for_paired_samples)

## Examples

```
>>> from scipy import stats
>>> np.random.seed(12345678) # fix random seed to get same numbers
```

```
>>> rvs1 = stats.norm.rvs(loc=5, scale=10, size=500)
>>> rvs2 = (stats.norm.rvs(loc=5, scale=10, size=500) +
... stats.norm.rvs(scale=0.2, size=500))
>>> stats.ttest_rel(rvs1, rvs2)
(0.24101764965300962, 0.80964043445811562)
>>> rvs3 = (stats.norm.rvs(loc=8, scale=10, size=500) +
... stats.norm.rvs(scale=0.2, size=500))
>>> stats.ttest_rel(rvs1, rvs3)
(-3.9995108708727933, 7.3082402191726459e-005)
```

**scipy.stats.kstest**

`scipy.stats.kstest` (*rvs*, *cdf*, *args=()*, *N=20*, *alternative='two-sided'*, *mode='approx'*)

Perform the Kolmogorov-Smirnov test for goodness of fit.

This performs a test of the distribution  $F(x)$  of an observed random variable against a given distribution  $G(x)$ . Under the null hypothesis the two distributions are identical,  $F(x)=G(x)$ . The alternative hypothesis can be either 'two-sided' (default), 'less' or 'greater'. The KS test is only valid for continuous distributions.

**Parameters**

<b>rvs</b>	[str, array or callable] If a string, it should be the name of a distribution in <code>scipy.stats</code> . If an array, it should be a 1-D array of observations of random variables. If a callable, it should be a function to generate random variables; it is required to have a keyword argument <i>size</i> .
<b>cdf</b>	[str or callable] If a string, it should be the name of a distribution in <code>scipy.stats</code> . If <i>rvs</i> is a string then <i>cdf</i> can be <code>False</code> or the same as <i>rvs</i> . If a callable, that callable is used to calculate the cdf.
<b>args</b>	[tuple, sequence, optional] Distribution parameters, used if <i>rvs</i> or <i>cdf</i> are strings.
<b>N</b>	[int, optional] Sample size if <i>rvs</i> is string or callable. Default is 20.
<b>alternative</b>	[{'two-sided', 'less', 'greater'}, optional] Defines the alternative hypothesis (see explanation above). Default is 'two-sided'.
<b>mode</b>	['approx' (default) or 'asympt', optional] Defines the distribution used for calculating the p-value. <ul style="list-style-type: none"> <li>• 'approx' : use approximation to exact distribution of test statistic</li> <li>• 'asympt' : use asymptotic distribution of test statistic</li> </ul>

**Returns**

<b>statistic</b>	[float] KS test statistic, either D, D+ or D-.
<b>pvalue</b>	[float] One-tailed or two-tailed p-value.

**Notes**

In the one-sided test, the alternative is that the empirical cumulative distribution function of the random variable is "less" or "greater" than the cumulative distribution function  $G(x)$  of the hypothesis,  $F(x) \leq G(x)$ , resp.  $F(x) \geq G(x)$ .

**Examples**

```
>>> from scipy import stats
```

```
>>> x = np.linspace(-15, 15, 9)
>>> stats.kstest(x, 'norm')
(0.44435602715924361, 0.038850142705171065)
```

```
>>> np.random.seed(987654321) # set random seed to get the same result
>>> stats.kstest('norm', False, N=100)
(0.058352892479417884, 0.88531190944151261)
```

The above lines are equivalent to:

```
>>> np.random.seed(987654321)
>>> stats.kstest(stats.norm.rvs(size=100), 'norm')
(0.058352892479417884, 0.88531190944151261)
```

*Test against one-sided alternative hypothesis*

Shift distribution to larger values, so that  $\text{cdf}_{\text{dgp}}(x) < \text{norm.cdf}(x)$ :

```
>>> np.random.seed(987654321)
>>> x = stats.norm.rvs(loc=0.2, size=100)
>>> stats.kstest(x, 'norm', alternative = 'less')
(0.12464329735846891, 0.040989164077641749)
```

Reject equal distribution against alternative hypothesis: less

```
>>> stats.kstest(x, 'norm', alternative = 'greater')
(0.0072115233216311081, 0.98531158590396395)
```

Don't reject equal distribution against alternative hypothesis: greater

```
>>> stats.kstest(x, 'norm', mode='asympt')
(0.12464329735846891, 0.08944488871182088)
```

*Testing t distributed random variables against normal distribution*

With 100 degrees of freedom the t distribution looks close to the normal distribution, and the K-S test does not reject the hypothesis that the sample came from the normal distribution:

```
>>> np.random.seed(987654321)
>>> stats.kstest(stats.t.rvs(100, size=100), 'norm')
(0.072018929165471257, 0.67630062862479168)
```

With 3 degrees of freedom the t distribution looks sufficiently different from the normal distribution, that we can reject the hypothesis that the sample came from the normal distribution at the 10% level:

```
>>> np.random.seed(987654321)
>>> stats.kstest(stats.t.rvs(3, size=100), 'norm')
(0.131016895759829, 0.05882622255312224)
```

## scipy.stats.chisquare

`scipy.stats.chisquare` (*f\_obs*, *f\_exp*=None, *ddof*=0, *axis*=0)

Calculate a one-way chi square test.

The chi square test tests the null hypothesis that the categorical data has the given frequencies.

### Parameters

- f\_obs** [array\_like] Observed frequencies in each category.
- f\_exp** [array\_like, optional] Expected frequencies in each category. By default the categories are assumed to be equally likely.
- ddof** [int, optional] “Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with  $k - 1 - \text{ddof}$  degrees of freedom, where  $k$  is the number of observed frequencies. The default value of *ddof* is 0.

**axis** [int or None, optional] The axis of the broadcast result of *f\_obs* and *f\_exp* along which to apply the test. If axis is None, all values in *f\_obs* are treated as a single data set. Default is 0.

**Returns**

**chisq** [float or ndarray] The chi-squared test statistic. The value is a float if *axis* is None or *f\_obs* and *f\_exp* are 1-D.  
**p** [float or ndarray] The p-value of the test. The value is a float if *ddof* and the return value *chisq* are scalars.

**See also:**

`scipy.stats.power_divergence`

**Notes**

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5.

The default degrees of freedom, *k*-1, are for the case when no parameters of the distribution are estimated. If *p* parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are *k*-1-*p*. If the parameters are estimated in a different way, then the dof can be between *k*-1-*p* and *k*-1. However, it is also possible that the asymptotic distribution is not a chisquare, in which case this test is not appropriate.

**References**

[1], [2]

**Examples**

When just *f\_obs* is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies.

```
>>> from scipy.stats import chisquare
>>> chisquare([16, 18, 16, 14, 12, 12])
(2.0, 0.84914503608460956)
```

With *f\_exp* the expected frequencies can be given.

```
>>> chisquare([16, 18, 16, 14, 12, 12], f_exp=[16, 16, 16, 16, 16, 8])
(3.5, 0.62338762774958223)
```

When *f\_obs* is 2-D, by default the test is applied to each column.

```
>>> obs = np.array([[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]])
>>> obs.shape
(6, 2)
>>> chisquare(obs)
(array([2. , 6.66666667]), array([0.84914504, 0.24663415]))
```

By setting *axis*=None, the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```
>>> chisquare(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> chisquare(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

*ddof* is the change to make to the default degrees of freedom.

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.73575888234288467)
```

The calculation of the p-values is done by broadcasting the chi-squared statistic with *ddof*.

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=[0, 1, 2])
(2.0, array([0.84914504, 0.73575888, 0.5724067]))
```

*f\_obs* and *f\_exp* are also broadcast. In the following, *f\_obs* has shape (6,) and *f\_exp* has shape (2, 6), so the result of broadcasting *f\_obs* and *f\_exp* has shape (2, 6). To compute the desired chi-squared statistics, we use `axis=1`:

```
>>> chisquare([16, 18, 16, 14, 12, 12],
... f_exp=[[16, 16, 16, 16, 16, 8], [8, 20, 20, 16, 12, 12]],
... axis=1)
(array([3.5 , 9.25]), array([0.62338763, 0.09949846]))
```

## scipy.stats.power\_divergence

`scipy.stats.power_divergence` (*f\_obs*, *f\_exp*=None, *ddof*=0, *axis*=0, *lambda\_*=None)

Cressie-Read power divergence statistic and goodness of fit test.

This function tests the null hypothesis that the categorical data has the given frequencies, using the Cressie-Read power divergence statistic.

### Parameters

- f\_obs** [array\_like] Observed frequencies in each category.
- f\_exp** [array\_like, optional] Expected frequencies in each category. By default the categories are assumed to be equally likely.
- ddof** [int, optional] “Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with  $k - 1 - \text{ddof}$  degrees of freedom, where  $k$  is the number of observed frequencies. The default value of *ddof* is 0.
- axis** [int or None, optional] The axis of the broadcast result of *f\_obs* and *f\_exp* along which to apply the test. If *axis* is None, all values in *f\_obs* are treated as a single data set. Default is 0.
- lambda\_** [float or str, optional] *lambda\_* gives the power in the Cressie-Read power divergence statistic. The default is 1. For convenience, *lambda\_* may be assigned one of the following strings, in which case the corresponding numerical value is used:

String	Value	Description
"pearson"	1	Pearson's chi-squared statistic.
"chisquare"		In this case, the function is equivalent to <code>stats.chisquare`</code> .
"log-likelihood"	0	Log-likelihood ratio. Also known as

(continues on next page)

(continued from previous page)

		the G-test [Rf6c2a1ea428c-3]_.
"freeman-tukey"	-1/2	Freeman-Tukey statistic.
"mod-log-likelihood"	-1	Modified log-likelihood ratio.
"neyman"	-2	Neyman's statistic.
"cressie-read"	2/3	The power recommended in [Rf6c2a1ea428c-5]_.

**Returns**

**statistic** [float or ndarray] The Cressie-Read power divergence test statistic. The value is a float if *axis* is None or if *f\_obs* and *f\_exp* are 1-D.

**pvalue** [float or ndarray] The p-value of the test. The value is a float if *ddof* and the return value *stat* are scalars.

**See also:***chisquare***Notes**

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5.

When *lambda\_* is less than zero, the formula for the statistic involves dividing by *f\_obs*, so a warning or error may be generated if any value in *f\_obs* is 0.

Similarly, a warning or error may be generated if any value in *f\_exp* is zero when *lambda\_*  $\geq$  0.

The default degrees of freedom, *k*-1, are for the case when no parameters of the distribution are estimated. If *p* parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are *k*-1-*p*. If the parameters are estimated in a different way, then the dof can be between *k*-1-*p* and *k*-1. However, it is also possible that the asymptotic distribution is not a chisquare, in which case this test is not appropriate.

This function handles masked arrays. If an element of *f\_obs* or *f\_exp* is masked, then data at that position is ignored, and does not count towards the size of the data set.

New in version 0.13.0.

**References**

[1], [2], [3], [4], [5]

**Examples**

(See *chisquare* for more examples.)

When just *f\_obs* is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies. Here we perform a G-test (i.e. use the log-likelihood ratio statistic):

```
>>> from scipy.stats import power_divergence
>>> power_divergence([16, 18, 16, 14, 12, 12], lambda_='log-likelihood')
(2.006573162632538, 0.84823476779463769)
```

The expected frequencies can be given with the *f\_exp* argument:

```
>>> power_divergence([16, 18, 16, 14, 12, 12],
... f_exp=[16, 16, 16, 16, 16, 8],
... lambda_='log-likelihood')
(3.3281031458963746, 0.6495419288047497)
```

When *f\_obs* is 2-D, by default the test is applied to each column.

```
>>> obs = np.array([[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]]).T
>>> obs.shape
(6, 2)
>>> power_divergence(obs, lambda_="log-likelihood")
(array([2.00657316, 6.77634498]), array([0.84823477, 0.23781225]))
```

By setting *axis=None*, the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```
>>> power_divergence(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> power_divergence(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

*ddof* is the change to make to the default degrees of freedom.

```
>>> power_divergence([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.73575888234288467)
```

The calculation of the p-values is done by broadcasting the test statistic with *ddof*.

```
>>> power_divergence([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([0.84914504, 0.73575888, 0.5724067]))
```

*f\_obs* and *f\_exp* are also broadcast. In the following, *f\_obs* has shape (6,) and *f\_exp* has shape (2, 6), so the result of broadcasting *f\_obs* and *f\_exp* has shape (2, 6). To compute the desired chi-squared statistics, we must use *axis=1*:

```
>>> power_divergence([16, 18, 16, 14, 12, 12],
... f_exp=[[16, 16, 16, 16, 16, 8],
... [8, 20, 20, 16, 12, 12]],
... axis=1)
(array([3.5 , 9.25]), array([0.62338763, 0.09949846]))
```

## scipy.stats.ks\_2samp

`scipy.stats.ks_2samp(data1, data2, alternative='two-sided', mode='auto')`

Compute the Kolmogorov-Smirnov statistic on 2 samples.

This is a two-sided test for the null hypothesis that 2 independent samples are drawn from the same continuous distribution. The alternative hypothesis can be either 'two-sided' (default), 'less' or 'greater'.

### Parameters

#### **data1, data2**

[sequence of 1-D ndarrays] Two arrays of sample observations assumed to be drawn from a continuous distribution, sample sizes can be different.

**alternative**

[[‘two-sided’, ‘less’, ‘greater’], optional] Defines the alternative hypothesis (see explanation above). Default is ‘two-sided’.

**mode**

[[‘auto’, ‘exact’, ‘asympt’], optional] Defines the method used for calculating the p-value. Default is ‘auto’.

- ‘exact’ : use approximation to exact distribution of test statistic
- ‘asympt’ : use asymptotic distribution of test statistic
- ‘auto’ : use ‘exact’ for small size arrays, ‘asympt’ for large.

**Returns**

**statistic** [float] KS statistic  
**pvalue** [float] two-tailed p-value

**Notes**

This tests whether 2 samples are drawn from the same distribution. Note that, like in the case of the one-sample K-S test, the distribution is assumed to be continuous.

In the one-sided test, the alternative is that the empirical cumulative distribution function  $F(x)$  of the data1 variable is “less” or “greater” than the empirical cumulative distribution function  $G(x)$  of the data2 variable,  $F(x) \leq G(x)$ , resp.  $F(x) \geq G(x)$ .

If the K-S statistic is small or the p-value is high, then we cannot reject the hypothesis that the distributions of the two samples are the same.

If the mode is ‘auto’, the computation is exact if the sample sizes are less than 10000. For larger sizes, the computation uses the Kolmogorov-Smirnov distributions to compute an approximate value.

We generally follow Hodges’ treatment of Drion/Gnedenko/Korolyuk [1].

**References**

[1]

**Examples**

```
>>> from scipy import stats
>>> np.random.seed(12345678) #fix random seed to get the same result
>>> n1 = 200 # size of first sample
>>> n2 = 300 # size of second sample
```

For a different distribution, we can reject the null hypothesis since the pvalue is below 1%:

```
>>> rvs1 = stats.norm.rvs(size=n1, loc=0., scale=1)
>>> rvs2 = stats.norm.rvs(size=n2, loc=0.5, scale=1.5)
>>> stats.ks_2samp(rvs1, rvs2)
(0.20833333333333334, 5.129279597781977e-05)
```

For a slightly different distribution, we cannot reject the null hypothesis at a 10% or lower alpha since the p-value at 0.144 is higher than 10%

```
>>> rvs3 = stats.norm.rvs(size=n2, loc=0.01, scale=1.0)
>>> stats.ks_2samp(rvs1, rvs3)
(0.10333333333333333, 0.14691437867433876)
```

For an identical distribution, we cannot reject the null hypothesis since the p-value is high, 41%:

```
>>> rvs4 = stats.norm.rvs(size=n2, loc=0.0, scale=1.0)
>>> stats.ks_2samp(rvs1, rvs4)
(0.079999999999999996, 0.41126949729859719)
```

## scipy.stats.epps\_singleton\_2samp

`scipy.stats.epps_singleton_2samp(x, y, t=(0.4, 0.8))`

Compute the Epps-Singleton (ES) test statistic.

Test the null hypothesis that two samples have the same underlying probability distribution.

### Parameters

<b>x, y</b>	[array-like] The two samples of observations to be tested. Input must not have more than one dimension. Samples can have different lengths.
<b>t</b>	[array-like, optional] The points ( $t_1, \dots, t_n$ ) where the empirical characteristic function is to be evaluated. It should be positive distinct numbers. The default value (0.4, 0.8) is proposed in [1]. Input must not have more than one dimension.

### Returns

<b>statistic</b>	[float] The test statistic.
<b>pvalue</b>	[float] The associated p-value based on the asymptotic chi2-distribution.

See also:

[\*ks\\_2samp\*](#), [\*anderson\\_ksamp\*](#)

## Notes

Testing whether two samples are generated by the same underlying distribution is a classical question in statistics. A widely used test is the Kolmogorov-Smirnov (KS) test which relies on the empirical distribution function. Epps and Singleton introduce a test based on the empirical characteristic function in [1].

One advantage of the ES test compared to the KS test is that it does not assume a continuous distribution. In [1], the authors conclude that the test also has a higher power than the KS test in many examples. They recommend the use of the ES test for discrete samples as well as continuous samples with at least 25 observations each, whereas [\*anderson\\_ksamp\*](#) is recommended for smaller sample sizes in the continuous case.

The p-value is computed from the asymptotic distribution of the test statistic which follows a *chi2* distribution. If the sample size of both  $x$  and  $y$  is below 25, the small sample correction proposed in [1] is applied to the test statistic.

The default values of  $t$  are determined in [1] by considering various distributions and finding good values that lead to a high power of the test in general. Table III in [1] gives the optimal values for the distributions tested in that study. The values of  $t$  are scaled by the semi-interquartile range in the implementation, see [1].

[1], [2]

## scipy.stats.mannwhitneyu

`scipy.stats.mannwhitneyu` (*x*, *y*, *use\_continuity*=*True*, *alternative*=*None*)

Compute the Mann-Whitney rank test on samples *x* and *y*.

### Parameters

- x, y** [array\_like] Array of samples, should be one-dimensional.
- use\_continuity** [bool, optional] Whether a continuity correction (1/2.) should be taken into account. Default is *True*.
- alternative** [None (deprecated), 'less', 'two-sided', or 'greater'] Whether to get the p-value for the one-sided hypothesis ('less' or 'greater') or for the two-sided hypothesis ('two-sided'). Defaults to *None*, which results in a p-value half the size of the 'two-sided' p-value and a different U statistic. The default behavior is not the same as using 'less' or 'greater': it only exists for backward compatibility and is deprecated.

### Returns

- statistic** [float] The Mann-Whitney U statistic, equal to  $\min(U \text{ for } x, U \text{ for } y)$  if *alternative* is equal to *None* (deprecated; exists for backward compatibility), and U for *y* otherwise.
- pvalue** [float] p-value assuming an asymptotic normal distribution. One-sided or two-sided, depending on the choice of *alternative*.

## Notes

Use only when the number of observation in each sample is  $> 20$  and you have 2 independent samples of ranks. Mann-Whitney U is significant if the u-obtained is LESS THAN or equal to the critical value of U.

This test corrects for ties and by default uses a continuity correction.

## References

[1], [2]

## scipy.stats.tiecorrect

`scipy.stats.tiecorrect` (*rankvals*)

Tie correction factor for ties in the Mann-Whitney U and Kruskal-Wallis H tests.

### Parameters

- rankvals** [array\_like] A 1-D sequence of ranks. Typically this will be the array returned by `rankdata`.

### Returns

- factor** [float] Correction factor for U or H.

See also:

### `rankdata`

Assign ranks to the data

**mannwhitneyu**

Mann-Whitney rank test

**kruskal**

Kruskal-Wallis H test

**References**

[1]

**Examples**

```

>>> from scipy.stats import tiecorrect, rankdata
>>> tiecorrect([1, 2.5, 2.5, 4])
0.9
>>> ranks = rankdata([1, 3, 2, 4, 5, 7, 2, 8, 4])
>>> ranks
array([1. , 4. , 2.5, 5.5, 7. , 8. , 2.5, 9. , 5.5])
>>> tiecorrect(ranks)
0.9833333333333333

```

**scipy.stats.rankdata**`scipy.stats.rankdata` (*a*, *method*='average')

Assign ranks to data, dealing with ties appropriately.

Ranks begin at 1. The *method* argument controls how ranks are assigned to equal values. See [1] for further discussion of ranking methods.**Parameters**

<b>a</b>	[array_like] The array of values to be ranked. The array is first flattened.
<b>method</b>	[str, optional] The method used to assign ranks to tied elements. The options are 'average', 'min', 'max', 'dense' and 'ordinal'. <ul style="list-style-type: none"> <li><b>'average':</b> The average of the ranks that would have been assigned to all the tied values is assigned to each value.</li> <li><b>'min':</b> The minimum of the ranks that would have been assigned to all the tied values is assigned to each value. (This is also referred to as "competition" ranking.)</li> <li><b>'max':</b> The maximum of the ranks that would have been assigned to all the tied values is assigned to each value.</li> <li><b>'dense':</b> Like 'min', but the rank of the next highest element is assigned the rank immediately after those assigned to the tied elements.</li> <li><b>'ordinal':</b> All values are given a distinct rank, corresponding to the order that the values occur in <i>a</i>.</li> </ul> The default is 'average'.

**Returns****ranks** [ndarray] An array of length equal to the size of *a*, containing rank scores.

## References

[1]

## Examples

```
>>> from scipy.stats import rankdata
>>> rankdata([0, 2, 3, 2])
array([1. , 2.5, 4. , 2.5])
>>> rankdata([0, 2, 3, 2], method='min')
array([1, 2, 4, 2])
>>> rankdata([0, 2, 3, 2], method='max')
array([1, 3, 4, 3])
>>> rankdata([0, 2, 3, 2], method='dense')
array([1, 2, 3, 2])
>>> rankdata([0, 2, 3, 2], method='ordinal')
array([1, 2, 4, 3])
```

## scipy.stats.ranksums

`scipy.stats.ranksums` (*x*, *y*)

Compute the Wilcoxon rank-sum statistic for two samples.

The Wilcoxon rank-sum test tests the null hypothesis that two sets of measurements are drawn from the same distribution. The alternative hypothesis is that values in one sample are more likely to be larger than the values in the other sample.

This test should be used to compare two samples from continuous distributions. It does not handle ties between measurements in *x* and *y*. For tie-handling and an optional continuity correction see [scipy.stats.mannwhitneyu](#).

### Parameters

**x,y** [array\_like] The data from the two samples

### Returns

**statistic** [float] The test statistic under the large-sample approximation that the rank sum statistic is normally distributed

**pvalue** [float] The two-sided p-value of the test

## References

[1]

## scipy.stats.wilcoxon

`scipy.stats.wilcoxon` (*x*, *y=None*, *zero\_method='wilcox'*, *correction=False*, *alternative='two-sided'*)

Calculate the Wilcoxon signed-rank test.

The Wilcoxon signed-rank test tests the null hypothesis that two related paired samples come from the same distribution. In particular, it tests whether the distribution of the differences *x* - *y* is symmetric about zero. It is a non-parametric version of the paired T-test.

**Parameters**

- x** [array\_like] Either the first set of measurements (in which case *y* is the second set of measurements), or the differences between two sets of measurements (in which case *y* is not to be specified.) Must be one-dimensional.
- y** [array\_like, optional] Either the second set of measurements (if *x* is the first set of measurements), or not specified (if *x* is the differences between two sets of measurements.) Must be one-dimensional.
- zero\_method** [{"pratt", "wilcox", "zsplit"}, optional. Default is "wilcox".]  
**"pratt"**: includes zero-differences in the ranking process, but drops the ranks of the zeros, see [4], (more conservative)  
**"wilcox"**: discards all zero-differences, the default  
**"zsplit"**: includes zero-differences in the ranking process and split the zero rank between positive and negative ones
- correction** [bool, optional] If True, apply continuity correction by adjusting the Wilcoxon rank statistic by 0.5 towards the mean value when computing the z-statistic. Default is False.
- alternative** [{"two-sided", "greater", "less"}, optional] The alternative hypothesis to be tested, see Notes. Default is "two-sided".

**Returns**

- statistic** [float] If *alternative* is "two-sided", the sum of the ranks of the differences above or below zero, whichever is smaller. Otherwise the sum of the ranks of the differences above zero.
- pvalue** [float] The p-value for the test depending on *alternative*.

**See also:**

*kruskal*, *mannwhitneyu*

**Notes**

The test has been introduced in [4]. Given *n* independent samples (*x<sub>i</sub>*, *y<sub>i</sub>*) from a bivariate distribution (i.e. paired samples), it computes the differences  $d_i = x_i - y_i$ . One assumption of the test is that the differences are symmetric, see [2]. The two-sided test has the null hypothesis that the median of the differences is zero against the alternative that it is different from zero. The one-sided test has the null hypothesis that the median is positive against the alternative that it is negative (`alternative == 'less'`), or vice versa (`alternative == 'greater'`).

The test uses a normal approximation to derive the p-value (if `zero_method == 'pratt'`, the approximation is adjusted as in [5]). A typical rule is to require that  $n > 20$  ([2], p. 383). For smaller *n*, exact tables can be used to find critical values.

**References**

[1], [2], [3], [4], [5]

**Examples**

In [4], the differences in height between cross- and self-fertilized corn plants is given as follows:

```
>>> d = [6, 8, 14, 16, 23, 24, 28, 29, 41, -48, 49, 56, 60, -67, 75]
```

Cross-fertilized plants appear to be higher. To test the null hypothesis that there is no height difference, we can apply the two-sided test:

```
>>> from scipy.stats import wilcoxon
>>> w, p = wilcoxon(d)
>>> w, p
(24.0, 0.04088813291185591)
```

Hence, we would reject the null hypothesis at a confidence level of 5%, concluding that there is a difference in height between the groups. To confirm that the median of the differences can be assumed to be positive, we use:

```
>>> w, p = wilcoxon(d, alternative='greater')
>>> w, p
(96.0, 0.020444066455927955)
```

This shows that the null hypothesis that the median is negative can be rejected at a confidence level of 5% in favor of the alternative that the median is greater than zero. The p-value based on the approximation is within the range of 0.019 and 0.054 given in [2]. Note that the statistic changed to 96 in the one-sided case (the sum of ranks of positive differences) whereas it is 24 in the two-sided case (the minimum of sum of ranks above and below zero).

## scipy.stats.kruskal

`scipy.stats.kruskal` (\*args, \*\*kwargs)

Compute the Kruskal-Wallis H-test for independent samples

The Kruskal-Wallis H-test tests the null hypothesis that the population median of all of the groups are equal. It is a non-parametric version of ANOVA. The test works on 2 or more independent samples, which may have different sizes. Note that rejecting the null hypothesis does not indicate which of the groups differs. Post-hoc comparisons between groups are required to determine which groups are different.

### Parameters

**sample1, sample2, ...**

[array\_like] Two or more arrays with the sample measurements can be given as arguments.

**nan\_policy**

[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

### Returns

**statistic** [float] The Kruskal-Wallis H statistic, corrected for ties

**pvalue** [float] The p-value for the test using the assumption that H has a chi square distribution

See also:

[f\\_oneway](#)

1-way ANOVA

[mannwhitneyu](#)

Mann-Whitney rank test on two samples.

[friedmanchisquare](#)

Friedman test for repeated measurements

## Notes

Due to the assumption that H has a chi square distribution, the number of samples in each group must not be too small. A typical rule is that each sample must have at least 5 measurements.

## References

[1], [2]

## Examples

```
>>> from scipy import stats
>>> x = [1, 3, 5, 7, 9]
>>> y = [2, 4, 6, 8, 10]
>>> stats.kruskal(x, y)
KruskalResult(statistic=0.2727272727272734, pvalue=0.6015081344405895)
```

```
>>> x = [1, 1, 1]
>>> y = [2, 2, 2]
>>> z = [2, 2]
>>> stats.kruskal(x, y, z)
KruskalResult(statistic=7.0, pvalue=0.0301973834223185)
```

## scipy.stats.friedmanchisquare

`scipy.stats.friedmanchisquare(*args)`

Compute the Friedman test for repeated measurements

The Friedman test tests the null hypothesis that repeated measurements of the same individuals have the same distribution. It is often used to test for consistency among measurements obtained in different ways. For example, if two measurement techniques are used on the same set of individuals, the Friedman test can be used to determine if the two measurement techniques are consistent.

### Parameters

**measurements1, measurements2, measurements3...**

[array\_like] Arrays of measurements. All of the arrays must have the same number of elements. At least 3 sets of measurements must be given.

### Returns

**statistic** [float] the test statistic, correcting for ties  
**pvalue** [float] the associated p-value assuming that the test statistic has a chi squared distribution

## Notes

Due to the assumption that the test statistic has a chi squared distribution, the p-value is only reliable for  $n > 10$  and more than 6 repeated measurements.

## References

[1]

**scipy.stats.brunnermunzel**

`scipy.stats.brunnermunzel(x, y, alternative='two-sided', distribution='t', nan_policy='propagate')`

Computes the Brunner-Munzel test on samples `x` and `y`

The Brunner-Munzel test is a nonparametric test of the null hypothesis that when values are taken one by one from each group, the probabilities of getting large values in both groups are equal. Unlike the Wilcoxon-Mann-Whitney's U test, this does not require the assumption of equivariance of two groups. Note that this does not assume the distributions are same. This test works on two independent samples, which may have different sizes.

**Parameters**

- x, y** [array\_like] Array of samples, should be one-dimensional.
- alternative** ['less', 'two-sided', or 'greater', optional] Whether to get the p-value for the one-sided hypothesis ('less' or 'greater') or for the two-sided hypothesis ('two-sided'). Defaults value is 'two-sided'.
- distribution: 't' or 'normal', optional**  
Whether to get the p-value by t-distribution or by standard normal distribution. Defaults value is 't'.
- nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

**Returns**

- statistic** [float] The Brunner-Munzer W statistic.
- pvalue** [float] p-value assuming an t distribution. One-sided or two-sided, depending on the choice of *alternative* and *distribution*.

See also:

**mannwhitneyu**

Mann-Whitney rank test on two samples.

**Notes**

Brunner and Munzel recommended to estimate the p-value by t-distribution when the size of data is 50 or less. If the size is lower than 10, it would be better to use permuted Brunner Munzel test (see [2]).

**References**

[1], [2]

**Examples**

```
>>> from scipy import stats
>>> x1 = [1, 2, 1, 1, 1, 1, 1, 1, 1, 1, 2, 4, 1, 1]
>>> x2 = [3, 3, 4, 3, 1, 2, 3, 1, 1, 5, 4]
>>> w, p_value = stats.brunnermunzel(x1, x2)
>>> w
3.1374674823029505
```

```

## scipy.stats.combine\_pvalues

`scipy.stats.combine_pvalues` (*pvalues*, *method*='fisher', *weights*=None)

Methods for combining the p-values of independent tests bearing upon the same hypothesis.

### Parameters

- |                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>pvalues</b>   | [array_like, 1-D] Array of p-values assumed to come from independent tests.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>method</b>    | [{'fisher', 'pearson', 'tippett', 'stouffer', 'mudholkar_george'},]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>optional.</b> | Name of method to use to combine p-values. The following methods are available: <ul style="list-style-type: none"> <li>“fisher”: Fisher’s method (Fisher’s combined probability test), the default, the sum of the logarithm of the p-values.</li> <li>“pearson”: Pearson’s method (similar to Fisher’s but uses sum of the complement of the p-values inside the logarithms).</li> <li>“tippett”: Tippett’s method (minimum of p-values).</li> <li>“stouffer”: Stouffer’s Z-score method.</li> <li>“<b>mudholkar_george</b>”: the difference of Fisher’s and Pearson’s methods divided by 2.</li> </ul> |
| <b>weights</b>   | [array_like, 1-D, optional] Optional array of weights used only for Stouffer’s Z-score method.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### Returns

- statistic: float** The statistic calculated by the specified method.
- pval: float** The combined p-value.

## Notes

Fisher’s method (also known as Fisher’s combined probability test) [1] uses a chi-squared statistic to compute a combined p-value. The closely related Stouffer’s Z-score method [2] uses Z-scores rather than p-values. The advantage of Stouffer’s method is that it is straightforward to introduce weights, which can make Stouffer’s method more powerful than Fisher’s method when the p-values are from studies of different size [6] [7]. The Pearson’s method uses  $\log(1 - p_i)$  inside the sum whereas Fisher’s method uses  $\log(p_i)$  [4]. For Fisher’s and Pearson’s method, the sum of the logarithms is multiplied by -2 in the implementation. This quantity has a chisquare distribution that determines the p-value. The *mudholkar\_george* method is the difference of the Fisher’s and Pearson’s test statistics, each of which include the -2 factor [4]. However, the *mudholkar\_george* method does not include these -2 factors. The test statistic of *mudholkar\_george* is the sum of logistic random variables and equation 3.6 in [3] is used to approximate the p-value based on Student’s t-distribution.

Fisher’s method may be extended to combine p-values from dependent tests [5]. Extensions such as Brown’s method and Kost’s method are not currently implemented.

New in version 0.15.0.

## scipy.stats.jarque\_bera

`scipy.stats.jarque_bera(x)`

Perform the Jarque-Bera goodness of fit test on sample data.

The Jarque-Bera test tests whether the sample data has the skewness and kurtosis matching a normal distribution.

Note that this test only works for a large enough number of data samples (>2000) as the test statistic asymptotically has a Chi-squared distribution with 2 degrees of freedom.

### Parameters

**x** [array\_like] Observations of a random variable.

### Returns

**jb\_value** [float] The test statistic.

**p** [float] The p-value for the hypothesis test.

**scipy.stats.ansari**`scipy.stats.ansari(x, y)`

Perform the Ansari-Bradley test for equal scale parameters

The Ansari-Bradley test is a non-parametric test for the equality of the scale parameter of the distributions from which two samples were drawn.

**Parameters****x, y** [array\_like] arrays of sample data**Returns**

**statistic** [float] The Ansari-Bradley test statistic  
**pvalue** [float] The p-value of the hypothesis test

**See also:****fligner**

A non-parametric test for the equality of k variances

**mood**

A non-parametric test for the equality of two scale parameters

**Notes**

The p-value given is exact when the sample sizes are both less than 55 and there are no ties, otherwise a normal approximation for the p-value is used.

**References**

[1]

**scipy.stats.bartlett**`scipy.stats.bartlett(*args)`

Perform Bartlett's test for equal variances

Bartlett's test tests the null hypothesis that all input samples are from populations with equal variances. For samples from significantly non-normal populations, Levene's test *levene* is more robust.

**Parameters**

**sample1, sample2,...**  
 [array\_like] arrays of sample data. Only 1d arrays are accepted, they may have different lengths.

**Returns**

**statistic** [float] The test statistic.  
**pvalue** [float] The p-value of the test.

**See also:****fligner**

A non-parametric test for the equality of k variances

## levene

A robust parametric test for equality of k variances

### Notes

Conover et al. (1981) examine many of the existing parametric and nonparametric tests by extensive simulations and they conclude that the tests proposed by Fligner and Killeen (1976) and Levene (1960) appear to be superior in terms of robustness of departures from normality and power ([3]).

### References

[1], [2], [3], [4]

## scipy.stats.levene

`scipy.stats.levene(*args, **kws)`  
Perform Levene test for equal variances.

The Levene test tests the null hypothesis that all input samples are from populations with equal variances. Levene's test is an alternative to Bartlett's test *bartlett* in the case where there are significant deviations from normality.

### Parameters

**sample1, sample2, ...**

[array\_like] The sample data, possibly with different lengths. Only one-dimensional samples are accepted.

**center** [{"mean", "median", "trimmed"}, optional] Which function of the data to use in the test. The default is 'median'.

**proportiontocut**

[float, optional] When *center* is 'trimmed', this gives the proportion of data points to cut from each end. (See *scipy.stats.trim\_mean*.) Default is 0.05.

### Returns

**statistic** [float] The test statistic.

**pvalue** [float] The p-value for the test.

### Notes

Three variations of Levene's test are possible. The possibilities and their recommended usages are:

- 'median' : Recommended for skewed (non-normal) distributions>
- 'mean' : Recommended for symmetric, moderate-tailed distributions.
- 'trimmed' : Recommended for heavy-tailed distributions.

The test version using the mean was proposed in the original article of Levene ([2]) while the median and trimmed mean have been studied by Brown and Forsythe ([3]), sometimes also referred to as Brown-Forsythe test.

### References

[1], [2], [3]

## scipy.stats.shapiro

`scipy.stats.shapiro(x)`

Perform the Shapiro-Wilk test for normality.

The Shapiro-Wilk test tests the null hypothesis that the data was drawn from a normal distribution.

### Parameters

**x** [array\_like] Array of sample data.

### Returns

**W** [float] The test statistic.

**p-value** [float] The p-value for the hypothesis test.

See also:

### anderson

The Anderson-Darling test for normality

### kstest

The Kolmogorov-Smirnov test for goodness of fit.

### Notes

The algorithm used is described in [4] but censoring parameters as described are not implemented. For  $N > 5000$  the  $W$  test statistic is accurate but the p-value may not be.

The chance of rejecting the null hypothesis when it is true is close to 5% regardless of sample size.

### References

[1], [2], [3], [4]

### Examples

```

>>> from scipy import stats
>>> np.random.seed(12345678)
>>> x = stats.norm.rvs(loc=5, scale=3, size=100)
>>> stats.shapiro(x)
(0.9772805571556091, 0.08144091814756393)

```

## scipy.stats.anderson

`scipy.stats.anderson(x, dist='norm')`

Anderson-Darling test for data coming from a particular distribution

The Anderson-Darling tests the null hypothesis that a sample is drawn from a population that follows a particular distribution. For the Anderson-Darling test, the critical values depend on which distribution is being tested against. This function works for normal, exponential, logistic, or Gumbel (Extreme Value Type I) distributions.

### Parameters

**x** [array\_like] array of sample data  
**dist** [{'norm', 'expon', 'logistic', 'gumbel', 'gumbel\_l', 'gumbel\_r',] 'extreme1'}, optional the type of distribution to test against. The default is 'norm' and 'extreme1', 'gumbel\_l' and 'gumbel' are synonyms.

**Returns**

**statistic** [float] The Anderson-Darling test statistic  
**critical\_values** [list] The critical values for this distribution  
**significance\_level** [list] The significance levels for the corresponding critical values in percents. The function returns critical values for a differing set of significance levels depending on the distribution that is being tested against.

**See also:**

**kstest**

The Kolmogorov-Smirnov test for goodness-of-fit.

**Notes**

Critical values provided are for the following significance levels:

*normal/exponential*

15%, 10%, 5%, 2.5%, 1%

*logistic*

25%, 10%, 5%, 2.5%, 1%, 0.5%

*Gumbel*

25%, 10%, 5%, 2.5%, 1%

If the returned statistic is larger than these critical values then for the corresponding significance level, the null hypothesis that the data come from the chosen distribution can be rejected. The returned statistic is referred to as 'A2' in the references.

**References**

[1], [2], [3], [4], [5], [6]

**scipy.stats.anderson\_ksamp**

`scipy.stats.anderson_ksamp` (*samples, midrank=True*)

The Anderson-Darling test for k-samples.

The k-sample Anderson-Darling test is a modification of the one-sample Anderson-Darling test. It tests the null hypothesis that k-samples are drawn from the same population without having to specify the distribution function of that population. The critical values depend on the number of samples.

**Parameters**

**samples** [sequence of 1-D array\_like] Array of sample data in arrays.

**midrank** [bool, optional] Type of Anderson-Darling test which is computed. Default (True) is the midrank test applicable to continuous and discrete populations. If False, the right side empirical distribution is used.

#### Returns

**statistic** [float] Normalized k-sample Anderson-Darling test statistic.

**critical\_values**

[array] The critical values for significance levels 25%, 10%, 5%, 2.5%, 1%.

**significance\_level**

[float] An approximate significance level at which the null hypothesis for the provided samples can be rejected. The value is floored / capped at 1% / 25%.

#### Raises

**ValueError**

If less than 2 samples are provided, a sample is empty, or no distinct observations are in the samples.

See also:

[ks\\_2samp](#)

2 sample Kolmogorov-Smirnov test

[anderson](#)

1 sample Anderson-Darling test

#### Notes

[1] defines three versions of the k-sample Anderson-Darling test: one for continuous distributions and two for discrete distributions, in which ties between samples may occur. The default of this routine is to compute the version based on the midrank empirical distribution function. This test is applicable to continuous and discrete data. If midrank is set to False, the right side empirical distribution is used for a test for discrete data. According to [1], the two discrete test statistics differ only slightly if a few collisions due to round-off errors occur in the test not adjusted for ties between samples.

The critical values corresponding to the significance levels from 0.01 to 0.25 are taken from [1]. p-values are floored / capped at 0.1% / 25%. Since the range of critical values might be extended in future releases, it is recommended not to test  $p == 0.25$ , but rather  $p >= 0.25$  (analogously for the lower bound).

New in version 0.14.0.

>>> np.random.seed(314159)
```

The null hypothesis that the two random samples come from the same distribution can be rejected at the 5% level because the returned test value is greater than the critical value for 5% (1.961) but not at the 2.5% level. The interpolation gives an approximate significance level of 3.2%:

```
>>> stats.anderson_ksamp([np.random.normal(size=50),
... np.random.normal(loc=0.5, size=30)])
(2.4615796189876105,
 array([0.325, 1.226, 1.961, 2.718, 3.752, 4.592, 6.546]),
 0.03176687568842282)
```

The null hypothesis cannot be rejected for three samples from an identical distribution. The reported p-value (25%) has been capped and may not be very accurate (since it corresponds to the value 0.449 whereas the statistic is -0.731):

```
>>> stats.anderson_ksamp([np.random.normal(size=50),
... np.random.normal(size=30), np.random.normal(size=20)])
(-0.73091722665244196,
 array([0.44925884, 1.3052767 , 1.9434184 , 2.57696569, 3.41634856,
 4.07210043, 5.56419101]),
 0.25)
```

## scipy.stats.binom\_test

`scipy.stats.binom_test(x, n=None, p=0.5, alternative='two-sided')`

Perform a test that the probability of success is  $p$ .

This is an exact, two-sided test of the null hypothesis that the probability of success in a Bernoulli experiment is  $p$ .

### Parameters

<b>x</b>	[integer or array_like] the number of successes, or if x has length 2, it is the number of successes and the number of failures.
<b>n</b>	[integer] the number of trials. This is ignored if x gives both the number of successes and failures
<b>p</b>	[float, optional] The hypothesized probability of success. $0 \leq p \leq 1$ . The default value is $p = 0.5$
<b>alternative</b>	[{'two-sided', 'greater', 'less'}, optional] Indicates the alternative hypothesis. The default value is 'two-sided'.

### Returns

<b>p-value</b>	[float] The p-value of the hypothesis test
----------------	--------------------------------------------

## References

[1]

## Examples

```
>>> from scipy import stats
```

A car manufacturer claims that no more than 10% of their cars are unsafe. 15 cars are inspected for safety, 3 were found to be unsafe. Test the manufacturer's claim:

```
>>> stats.binom_test(3, n=15, p=0.1, alternative='greater')
0.18406106910639114
```

The null hypothesis cannot be rejected at the 5% level of significance because the returned p-value is greater than the critical value of 5%.

## scipy.stats.fligner

`scipy.stats.fligner(*args, **kwargs)`

Perform Fligner-Killeen test for equality of variance.

Fligner's test tests the null hypothesis that all input samples are from populations with equal variances. Fligner-Killeen's test is distribution free when populations are identical [2].

### Parameters

**sample1, sample2, ...**

[array\_like] Arrays of sample data. Need not be the same length.

**center** [ {'mean', 'median', 'trimmed'}, optional] Keyword argument controlling which function of the data is used in computing the test statistic. The default is 'median'.

**proportiontocut**

[float, optional] When *center* is 'trimmed', this gives the proportion of data points to cut from each end. (See `scipy.stats.trim_mean`.) Default is 0.05.

### Returns

**statistic** [float] The test statistic.

**pvalue** [float] The p-value for the hypothesis test.

See also:

## bartlett

A parametric test for equality of k variances in normal samples

## levene

A robust parametric test for equality of k variances

## Notes

As with Levene's test there are three variants of Fligner's test that differ by the measure of central tendency used in the test. See `levene` for more information.

Conover et al. (1981) examine many of the existing parametric and nonparametric tests by extensive simulations and they conclude that the tests proposed by Fligner and Killeen (1976) and Levene (1960) appear to be superior in terms of robustness of departures from normality and power [3].

## scipy.stats.median\_test

`scipy.stats.median_test(*args, **kwargs)`

Mood's median test.

Test that two or more samples come from populations with the same median.

Let  $n = \text{len}(\text{args})$  be the number of samples. The “grand median” of all the data is computed, and a contingency table is formed by classifying the values in each sample as being above or below the grand median. The contingency table, along with *correction* and *lambda\_*, are passed to `scipy.stats.chi2_contingency` to compute the test statistic and p-value.

### Parameters

#### **sample1, sample2, ...**

[array\_like] The set of samples. There must be at least two samples. Each sample must be a one-dimensional sequence containing at least one value. The samples are not required to have the same length.

#### **ties**

[str, optional] Determines how values equal to the grand median are classified in the contingency table. The string must be one of:

```
"below":
 Values equal to the grand median are counted as "below
↪".
"above":
 Values equal to the grand median are counted as "above
↪".
"ignore":
 Values equal to the grand median are not counted.
```

The default is “below”.

**correction** [bool, optional] If True, *and* there are just two samples, apply Yates’ correction for continuity when computing the test statistic associated with the contingency table. Default is True.

**lambda\_** [float or str, optional.] By default, the statistic computed in this test is Pearson’s chi-squared statistic. *lambda\_* allows a statistic from the Cressie-Read power divergence family to be used instead. See [power\\_divergence](#) for details. Default is 1 (Pearson’s chi-squared statistic).

#### **nan\_policy**

[{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

### Returns

**stat** [float] The test statistic. The statistic that is returned is determined by *lambda\_*. The default is Pearson’s chi-squared statistic.

**p** [float] The p-value of the test.

**m** [float] The grand median.

**table** [ndarray] The contingency table. The shape of the table is (2, n), where n is the number of samples. The first row holds the counts of the values above the grand median, and the second row holds the counts of the values below the grand median. The table allows further analysis with, for example, `scipy.stats.chi2_contingency`, or with `scipy.stats.fisher_exact` if there are two samples, without having to recompute the table. If *nan\_policy* is “propagate” and there are nans in the input, the return value for *table* is None.

#### [kruskal](#)

Compute the Kruskal-Wallis H-test for independent samples.

#### [mannwhitneyu](#)

Computes the Mann-Whitney rank test on samples x and y.

## Notes

New in version 0.15.0.

## References

[1], [2]

## Examples

A biologist runs an experiment in which there are three groups of plants. Group 1 has 16 plants, group 2 has 15 plants, and group 3 has 17 plants. Each plant produces a number of seeds. The seed counts for each group are:

```
Group 1: 10 14 14 18 20 22 24 25 31 31 32 39 43 43 48 49
Group 2: 28 30 31 33 34 35 36 40 44 55 57 61 91 92 99
Group 3: 0 3 9 22 23 25 25 33 34 34 40 45 46 48 62 67 84
```

The following code applies Mood's median test to these samples.

```
>>> g1 = [10, 14, 14, 18, 20, 22, 24, 25, 31, 31, 32, 39, 43, 43, 48, 49]
>>> g2 = [28, 30, 31, 33, 34, 35, 36, 40, 44, 55, 57, 61, 91, 92, 99]
>>> g3 = [0, 3, 9, 22, 23, 25, 25, 33, 34, 34, 40, 45, 46, 48, 62, 67, 84]
>>> from scipy.stats import median_test
>>> stat, p, med, tbl = median_test(g1, g2, g3)
```

The median is

```
>>> med
34.0
```

and the contingency table is

```
>>> tbl
array([[5, 10, 7],
 [11, 5, 10]])
```

$p$  is too large to conclude that the medians are not the same:

```
>>> p
0.12609082774093244
```

The “G-test” can be performed by passing `lambda_="log-likelihood"` to `median_test`.

```
>>> g, p, med, tbl = median_test(g1, g2, g3, lambda_="log-likelihood")
>>> p
0.12224779737117837
```

The median occurs several times in the data, so we'll get a different result if, for example, `ties="above"` is used:

```
>>> stat, p, med, tbl = median_test(g1, g2, g3, ties="above")
>>> p
0.063873276069553273
```

```
>>> tbl
array([[5, 11, 9],
 [11, 4, 8]])
```

This example demonstrates that if the data set is not large and there are values equal to the median, the p-value can be sensitive to the choice of *ties*.

## scipy.stats.mood

`scipy.stats.mood(x, y, axis=0)`

Perform Mood's test for equal scale parameters.

Mood's two-sample test for scale parameters is a non-parametric test for the null hypothesis that two samples are drawn from the same distribution with the same scale parameter.

### Parameters

<b>x, y</b>	[array_like] Arrays of sample data.
<b>axis</b>	[int, optional] The axis along which the samples are tested. <i>x</i> and <i>y</i> can be of different length along <i>axis</i> . If <i>axis</i> is None, <i>x</i> and <i>y</i> are flattened and the test is done on all values in the flattened arrays.

### Returns

<b>z</b>	[scalar or ndarray] The z-score for the hypothesis test. For 1-D inputs a scalar is returned.
<b>p-value</b>	[scalar ndarray] The p-value for the hypothesis test.

See also:

### [fligner](#)

A non-parametric test for the equality of k variances

### [ansari](#)

A non-parametric test for the equality of 2 variances

### [bartlett](#)

A parametric test for equality of k variances in normal samples

### [levene](#)

A parametric test for equality of k variances

## Notes

The data are assumed to be drawn from probability distributions  $f(x)$  and  $f(x/s) / s$  respectively, for some probability density function  $f$ . The null hypothesis is that  $s == 1$ .

For multi-dimensional arrays, if the inputs are of shapes  $(n_0, n_1, n_2, n_3)$  and  $(n_0, m_1, n_2, n_3)$ , then if `axis=1`, the resulting *z* and *p* values will have shape  $(n_0, n_2, n_3)$ . Note that *n1* and *m1* don't have to be equal, but the other dimensions do.

## Examples

```

>>> from scipy import stats
>>> np.random.seed(1234)
>>> x2 = np.random.randn(2, 45, 6, 7)
>>> x1 = np.random.randn(2, 30, 6, 7)
>>> z, p = stats.mood(x1, x2, axis=1)
>>> p.shape
(2, 6, 7)

```

Find the number of points where the difference in scale is not significant:

```

>>> (p > 0.1).sum()
74

```

Perform the test with different scales:

```

>>> x1 = np.random.randn(2, 30)
>>> x2 = np.random.randn(2, 35) * 10.0
>>> stats.mood(x1, x2, axis=1)
(array([-5.7178125 , -5.25342163]), array([1.07904114e-08, 1.
→49299218e-07]))

```

## scipy.stats.skewtest

`scipy.stats.skewtest` (*a*, *axis=0*, *nan\_policy='propagate'*)

Test whether the skew is different from the normal distribution.

This function tests the null hypothesis that the skewness of the population that the sample was drawn from is the same as that of a corresponding normal distribution.

### Parameters

- a** [array] The data to be tested
- axis** [int or None, optional] Axis along which statistics are calculated. Default is 0. If None, compute over the whole array *a*.
- nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

### Returns

- statistic** [float] The computed z-score for this test.
- pvalue** [float] a 2-sided p-value for the hypothesis test

## Notes

The sample size must be at least 8.

## References

[1]

## Examples

```
>>> from scipy.stats import skewtest
>>> skewtest([1, 2, 3, 4, 5, 6, 7, 8])
SkewtestResult(statistic=1.0108048609177787, pvalue=0.3121098361421897)
>>> skewtest([2, 8, 0, 4, 1, 9, 9, 0])
SkewtestResult(statistic=0.44626385374196975, pvalue=0.6554066631275459)
>>> skewtest([1, 2, 3, 4, 5, 6, 7, 8000])
SkewtestResult(statistic=3.571773510360407, pvalue=0.0003545719905823133)
>>> skewtest([100, 100, 100, 100, 100, 100, 100, 101])
SkewtestResult(statistic=3.5717766638478072, pvalue=0.000354567720281634)
```

## scipy.stats.kurtosistest

`scipy.stats.kurtosistest` (*a*, *axis*=0, *nan\_policy*='propagate')

Test whether a dataset has normal kurtosis.

This function tests the null hypothesis that the kurtosis of the population from which the sample was drawn is that of the normal distribution:  $kurtosis = 3(n-1)/(n+1)$ .

### Parameters

**a** [array] array of the sample data

**axis** [int or None, optional] Axis along which to compute test. Default is 0. If None, compute over the whole array *a*.

**nan\_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

### Returns

**statistic** [float] The computed z-score for this test.

**pvalue** [float] The 2-sided p-value for the hypothesis test

## Notes

Valid only for  $n > 20$ . This function uses the method described in [1].

## References

[1]

## Examples

```
>>> from scipy.stats import kurtosistest
>>> kurtosistest(list(range(20)))
KurtosistestResult(statistic=-1.7058104152122062, pvalue=0.
→08804338332528348)
```

```

>>> np.random.seed(28041990)
>>> s = np.random.normal(0, 1, 1000)
>>> kurtosistest(s)
KurtosistestResult(statistic=1.2317590987707365, pvalue=0.
→21803908613450895)

```

## scipy.stats.normaltest

`scipy.stats.normaltest` (*a*, *axis*=0, *nan\_policy*='propagate')

Test whether a sample differs from a normal distribution.

This function tests the null hypothesis that a sample comes from a normal distribution. It is based on D'Agostino and Pearson's [1], [2] test that combines skew and kurtosis to produce an omnibus test of normality.

### Parameters

- a** [array\_like] The array containing the sample to be tested.
- axis** [int or None, optional] Axis along which to compute test. Default is 0. If None, compute over the whole array *a*.
- nan\_policy** [{ 'propagate', 'raise', 'omit' }, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

### Returns

- statistic** [float or array]  $s^2 + k^2$ , where *s* is the z-score returned by `skewtest` and *k* is the z-score returned by `kurtosistest`.
- pvalue** [float or array] A 2-sided chi squared probability for the hypothesis test.

## References

[1], [2]

## Examples

```

>>> from scipy import stats
>>> pts = 1000
>>> np.random.seed(28041990)
>>> a = np.random.normal(0, 1, size=pts)
>>> b = np.random.normal(2, 1, size=pts)
>>> x = np.concatenate((a, b))
>>> k2, p = stats.normaltest(x)
>>> alpha = 1e-3
>>> print("p = {:g}".format(p))
p = 3.27207e-11
>>> if p < alpha: # null hypothesis: x comes from a normal distribution
... print("The null hypothesis can be rejected")
... else:
... print("The null hypothesis cannot be rejected")
The null hypothesis can be rejected

```

## 6.28.11 Transformations

<code>boxcox(x[, lmbda, alpha])</code>	Return a positive dataset transformed by a Box-Cox power transformation.
<code>boxcox_normmax(x[, brack, method])</code>	Compute optimal Box-Cox transform parameter for input data.
<code>boxcox_llf(lmb, data)</code>	The boxcox log-likelihood function.
<code>yeojohnson(x[, lmbda])</code>	Return a dataset transformed by a Yeo-Johnson power transformation.
<code>yeojohnson_normmax(x[, brack])</code>	Compute optimal Yeo-Johnson transform parameter for input data, using maximum likelihood estimation.
<code>yeojohnson_llf(lmb, data)</code>	The yeojohnson log-likelihood function.
<code>obrientransform(*args)</code>	Compute the O'Brien transform on input data (any number of arrays).
<code>sigmaclip(a[, low, high])</code>	Iterative sigma-clipping of array elements.
<code>trimboth(a, proportiontocut[, axis])</code>	Slices off a proportion of items from both ends of an array.
<code>trim1(a, proportiontocut[, tail, axis])</code>	Slices off a proportion from ONE end of the passed array distribution.
<code>zmap(scores, compare[, axis, ddof])</code>	Calculate the relative z-scores.
<code>zscore(a[, axis, ddof])</code>	Calculate the z score of each value in the sample, relative to the sample mean and standard deviation.

### scipy.stats.boxcox

`scipy.stats.boxcox(x, lmbda=None, alpha=None)`

Return a positive dataset transformed by a Box-Cox power transformation.

#### Parameters

- x** [ndarray] Input array. Should be 1-dimensional.
- lmbda** [{None, scalar}, optional] If *lmbda* is not None, do the transformation for that value. If *lmbda* is None, find the lambda that maximizes the log-likelihood function and return it as the second output argument.
- alpha** [{None, float}, optional] If *alpha* is not None, return the  $100 * (1-\alpha)\%$  confidence interval for *lmbda* as the third output argument. Must be between 0.0 and 1.0.

#### Returns

- boxcox** [ndarray] Box-Cox power transformed array.
- maxlog** [float, optional] If the *lmbda* parameter is None, the second returned argument is the lambda that maximizes the log-likelihood function.
- (min\_ci, max\_ci)** [tuple of float, optional] If *lmbda* parameter is None and *alpha* is not None, this returned tuple of floats represents the minimum and maximum confidence limits given *alpha*.

#### See also:

`probplot`, `boxcox_normplot`, `boxcox_normmax`, `boxcox_llf`

#### Notes

The Box-Cox transform is given by:

```
y = (x**lambda - 1) / lambda, for lambda > 0
 log(x), for lambda = 0
```

`boxcox` requires the input data to be positive. Sometimes a Box-Cox transformation provides a shift parameter to achieve this; `boxcox` does not. Such a shift parameter is equivalent to adding a positive constant to  $x$  before calling `boxcox`.

The confidence limits returned when `alpha` is provided give the interval where:

$$llf(\hat{\lambda}) - llf(\lambda) < \frac{1}{2}\chi^2(1 - \alpha, 1),$$

with `llf` the log-likelihood function and  $\chi^2$  the chi-squared function.

## References

G.E.P. Box and D.R. Cox, “An Analysis of Transformations”, *Journal of the Royal Statistical Society B*, 26, 211-252 (1964).

## Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

We generate some random variates from a non-normal distribution and make a probability plot for it, to show it is non-normal in the tails:

```
>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(211)
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> prob = stats.probplot(x, dist=stats.norm, plot=ax1)
>>> ax1.set_xlabel('')
>>> ax1.set_title('Probplot against normal distribution')
```

We now use `boxcox` to transform the data so it's closest to normal:

```
>>> ax2 = fig.add_subplot(212)
>>> xt, _ = stats.boxcox(x)
>>> prob = stats.probplot(xt, dist=stats.norm, plot=ax2)
>>> ax2.set_title('Probplot after Box-Cox transformation')
```

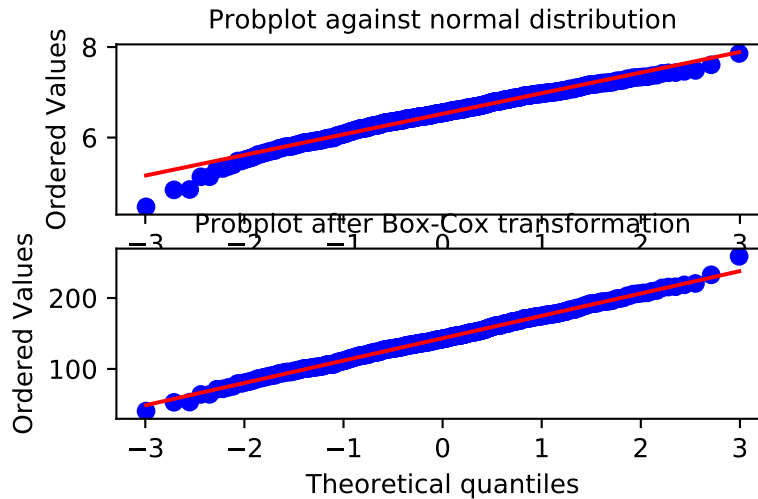

```
>>> plt.show()
```

## `scipy.stats.boxcox_normmax`

`scipy.stats.boxcox_normmax(x, brack=(-2.0, 2.0), method='pearsonr')`  
Compute optimal Box-Cox transform parameter for input data.

### Parameters

<b>x</b>	[array_like] Input array.
<b>brack</b>	[2-tuple, optional] The starting interval for a downhill bracket search with <code>optimize.brent</code> . Note that this is in most cases not critical; the final result is allowed to be outside this bracket.

- method** [str, optional] The method to determine the optimal transform parameter (`boxcox` lambda parameter). Options are:
- 'pearsonr'** (default) Maximizes the Pearson correlation coefficient between  $y = \text{boxcox}(x)$  and the expected values for  $y$  if  $x$  would be normally-distributed.
  - 'mle'** Minimizes the log-likelihood `boxcox_llf`. This is the method used in `boxcox`.
  - 'all'** Use all optimization methods available, and return all results. Useful to compare different methods.

#### Returns

- maxlog** [float or ndarray] The optimal transform parameter found. An array instead of a scalar for `method='all'`.

#### See also:

`boxcox`, `boxcox_llf`, `boxcox_normplot`

#### Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234) # make this example reproducible
```

Generate some data and determine optimal lambda in various ways:

```
>>> x = stats.loggamma.rvs(5, size=30) + 5
>>> y, lmax_mle = stats.boxcox(x)
>>> lmax_pearsonr = stats.boxcox_normmax(x)
```

```
>>> lmax_mle
7.177...
>>> lmax_pearsonr
```

(continues on next page)

(continued from previous page)

```
7.916...
>>> stats.boxcox_normmax(x, method='all')
array([7.91667384, 7.17718692])
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.boxcox_normplot(x, -10, 10, plot=ax)
>>> ax.axvline(lmax_mle, color='r')
>>> ax.axvline(lmax_pearsonr, color='g', ls='--')
```

```
>>> plt.show()
```

## scipy.stats.boxcox\_llf

`scipy.stats.boxcox_llf(lmb, data)`

The boxcox log-likelihood function.

### Parameters

**lmb** [scalar] Parameter for Box-Cox transformation. See [boxcox](#) for details.  
**data** [array\_like] Data to calculate Box-Cox log-likelihood for. If *data* is multi-dimensional, the log-likelihood is calculated along the first axis.

### Returns

**llf** [float or ndarray] Box-Cox log-likelihood of *data* given *lmb*. A float for 1-D *data*, an array otherwise.

### See also:

[boxcox](#), [probplot](#), [boxcox\\_normplot](#), [boxcox\\_normmax](#)

## Notes

The Box-Cox log-likelihood function is defined here as

$$llf = (\lambda - 1) \sum_i (\log(x_i)) - N/2 \log(\sum_i (y_i - \bar{y})^2 / N),$$

where  $y$  is the Box-Cox transformed input data  $x$ .

## Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> from mpl_toolkits.axes_grid1.inset_locator import inset_axes
>>> np.random.seed(1245)
```

Generate some random variates and calculate Box-Cox log-likelihood values for them for a range of lambda values:

```
>>> x = stats.loggamma.rvs(5, loc=10, size=1000)
>>> lmbdas = np.linspace(-2, 10)
>>> llf = np.zeros(lmbdas.shape, dtype=float)
>>> for ii, lambda in enumerate(lmbdas):
... llf[ii] = stats.boxcox_llf(lambda, x)
```

Also find the optimal lambda value with `boxcox`:

```
>>> x_most_normal, lambda_optimal = stats.boxcox(x)
```

Plot the log-likelihood as function of lambda. Add the optimal lambda as a horizontal line to check that that's really the optimum:

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(lmbdas, llf, 'b.-')
>>> ax.axhline(stats.boxcox_llf(lambda_optimal, x), color='r')
>>> ax.set_xlabel('lambda parameter')
>>> ax.set_ylabel('Box-Cox log-likelihood')
```

Now add some probability plots to show that where the log-likelihood is maximized the data transformed with `boxcox` looks closest to normal:

```
>>> locs = [3, 10, 4] # 'lower left', 'center', 'lower right'
>>> for lambda, loc in zip([-1, lambda_optimal, 9], locs):
... xt = stats.boxcox(x, lambda=lambda)
... (osm, osr), (slope, intercept, r_sq) = stats.probplot(xt)
... ax_inset = inset_axes(ax, width="20%", height="20%", loc=loc)
... ax_inset.plot(osm, osr, 'c.', osm, slope*osm + intercept, 'k-')
... ax_inset.set_xticklabels([])
... ax_inset.set_yticklabels([])
... ax_inset.set_title(r'$\lambda = %1.2f$' % lambda)
```

```
>>> plt.show()
```

## scipy.stats.yeojohnson

`scipy.stats.yeojohnson` (*x*, *lmbda*=None)

Return a dataset transformed by a Yeo-Johnson power transformation.

### Parameters

- x** [ndarray] Input array. Should be 1-dimensional.
- lmbda** [float, optional] If *lmbda* is None, find the lambda that maximizes the log-likelihood function and return it as the second output argument. Otherwise the transformation is done for the given value.

### Returns

- yeojohnson:** ndarray  
Yeo-Johnson power transformed array.
- maxlog** [float, optional] If the *lmbda* parameter is None, the second returned argument is the lambda that maximizes the log-likelihood function.

### See also:

[probplot](#), [yeojohnson\\_normplot](#), [yeojohnson\\_normmax](#), [yeojohnson\\_llf](#), [boxcox](#)

### Notes

The Yeo-Johnson transform is given by:

$y = ((x + 1)**lmbda - 1) / lmbda,$	<b>for</b> $x \geq 0, lmbda \neq 0$
$\log(x + 1),$	<b>for</b> $x \geq 0, lmbda = 0$
$-((-x + 1)**(2 - lmbda) - 1) / (2 - lmbda),$	<b>for</b> $x < 0, lmbda \neq 2$
$-\log(-x + 1),$	<b>for</b> $x < 0, lmbda = 2$

Unlike [boxcox](#), [yeojohnson](#) does not require the input data to be positive.

New in version 1.2.0.

## References

I. Yeo and R.A. Johnson, “A New Family of Power Transformations to Improve Normality or Symmetry”, *Biometrika* 87.4 (2000):

## Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

We generate some random variates from a non-normal distribution and make a probability plot for it, to show it is non-normal in the tails:

```
>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(211)
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> prob = stats.probplot(x, dist=stats.norm, plot=ax1)
>>> ax1.set_xlabel('')
>>> ax1.set_title('Probplot against normal distribution')
```

We now use `yeojohnson` to transform the data so it's closest to normal:

```
>>> ax2 = fig.add_subplot(212)
>>> xt, lambda = stats.yeojohnson(x)
>>> prob = stats.probplot(xt, dist=stats.norm, plot=ax2)
>>> ax2.set_title('Probplot after Yeo-Johnson transformation')
```

```
>>> plt.show()
```

### `scipy.stats.yeojohnson_normmax`

```
scipy.stats.yeojohnson_normmax(x, brack=(-2, 2))
```

Compute optimal Yeo-Johnson transform parameter for input data, using maximum likelihood estimation.

**Parameters**

- x** [array\_like] Input array.
- brack** [2-tuple, optional] The starting interval for a downhill bracket search with *optimize.brent*. Note that this is in most cases not critical; the final result is allowed to be outside this bracket.

**Returns**

- maxlog** [float] The optimal transform parameter found.

**See also:**

*yeojohnson*, *yeojohnson\_llf*, *yeojohnson\_normplot*

**Notes**

New in version 1.2.0.

**Examples**

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234) # make this example reproducible
```

Generate some data and determine optimal lambda

```
>>> x = stats.loggamma.rvs(5, size=30) + 5
>>> lmax = stats.yeojohnson_normmax(x)
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.yeojohnson_normplot(x, -10, 10, plot=ax)
>>> ax.axvline(lmax, color='r')
```

```
>>> plt.show()
```

**scipy.stats.yeojohnson\_llf**

`scipy.stats.yeojohnson_llf(lmb, data)`

The yeojohnson log-likelihood function.

**Parameters**

- lmb** [scalar] Parameter for Yeo-Johnson transformation. See *yeojohnson* for details.
- data** [array\_like] Data to calculate Yeo-Johnson log-likelihood for. If *data* is multi-dimensional, the log-likelihood is calculated along the first axis.

**Returns**

- llf** [float] Yeo-Johnson log-likelihood of *data* given *lmb*.

**See also:**

*yeojohnson*, *probplot*, *yeojohnson\_normplot*, *yeojohnson\_normmax*

## Notes

The Yeo-Johnson log-likelihood function is defined here as

$$llf = N/2 \log(\hat{\sigma}^2) + (\lambda - 1) \sum_i \text{sign}(x_i) \log(|x_i| + 1)$$

where  $\hat{\sigma}^2$  is estimated variance of the the Yeo-Johnson transformed input data  $x$ .

New in version 1.2.0.

## Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> from mpl_toolkits.axes_grid1.inset_locator import inset_axes
>>> np.random.seed(1245)
```

Generate some random variates and calculate Yeo-Johnson log-likelihood values for them for a range of lambda values:

```
>>> x = stats.loggamma.rvs(5, loc=10, size=1000)
>>> lmbdas = np.linspace(-2, 10)
>>> llf = np.zeros(lmbdas.shape, dtype=float)
>>> for ii, lambda in enumerate(lmbdas):
... llf[ii] = stats.yeojohnson_llf(lambda, x)
```

Also find the optimal lambda value with `yeojohnson`:

```
>>> x_most_normal, lambda_optimal = stats.yeojohnson(x)
```

Plot the log-likelihood as function of lambda. Add the optimal lambda as a horizontal line to check that that's really the optimum:

```

>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(lmbdas, llf, 'b.-')
>>> ax.axhline(stats.yeojohnson_llf(lambda_optimal, x), color='r')
>>> ax.set_xlabel('lambda parameter')
>>> ax.set_ylabel('Yeo-Johnson log-likelihood')

```

Now add some probability plots to show that where the log-likelihood is maximized the data transformed with *yeojohnson* looks closest to normal:

```

>>> locs = [3, 10, 4] # 'lower left', 'center', 'lower right'
>>> for lambda, loc in zip([-1, lambda_optimal, 9], locs):
... xt = stats.yeojohnson(x, lambda=lambda)
... (osm, osr), (slope, intercept, r_sq) = stats.probplot(xt)
... ax_inset = inset_axes(ax, width="20%", height="20%", loc=loc)
... ax_inset.plot(osm, osr, 'c.', osm, slope*osm + intercept, 'k-')
... ax_inset.set_xticklabels([])
... ax_inset.set_yticklabels([])
... ax_inset.set_title(r'$\lambda=%1.2f$' % lambda)

```

```

>>> plt.show()

```

### scipy.stats.obrienttransform

`scipy.stats.obrienttransform(*args)`

Compute the O'Brien transform on input data (any number of arrays).

Used to test for homogeneity of variance prior to running one-way stats. Each array in *\*args* is one level of a factor. If *f\_oneway* is run on the transformed data and found significant, the variances are unequal. From Maxwell and Delaney [1], p.112.

#### Parameters

**args** [tuple of array\_like] Any number of arrays.

**Returns****obrientransform**

[ndarray] Transformed data for use in an ANOVA. The first dimension of the result corresponds to the sequence of transformed arrays. If the arrays given are all 1-D of the same length, the return value is a 2-D array; otherwise it is a 1-D array of type object, with each element being an ndarray.

**References**

[1]

**Examples**

We'll test the following data sets for differences in their variance.

```
>>> x = [10, 11, 13, 9, 7, 12, 12, 9, 10]
>>> y = [13, 21, 5, 10, 8, 14, 10, 12, 7, 15]
```

Apply the O'Brien transform to the data.

```
>>> from scipy.stats import obrientransform
>>> tx, ty = obrientransform(x, y)
```

Use `scipy.stats.f_oneway` to apply a one-way ANOVA test to the transformed data.

```
>>> from scipy.stats import f_oneway
>>> F, p = f_oneway(tx, ty)
>>> p
0.1314139477040335
```

If we require that  $p < 0.05$  for significance, we cannot conclude that the variances are different.

**scipy.stats.sigmaclip**

`scipy.stats.sigmaclip` (*a*, *low*=4.0, *high*=4.0)

Iterative sigma-clipping of array elements.

Starting from the full sample, all elements outside the critical range are removed, i.e. all elements of the input array *c* that satisfy either of the following conditions

```
c < mean(c) - std(c)*low
c > mean(c) + std(c)*high
```

The iteration continues with the updated sample until no elements are outside the (updated) range.

**Parameters**

**a** [array\_like] Data array, will be raveled if not 1-D.  
**low** [float, optional] Lower bound factor of sigma clipping. Default is 4.  
**high** [float, optional] Upper bound factor of sigma clipping. Default is 4.

**Returns**

**clipped** [ndarray] Input array with clipped elements removed.

**lower** [float] Lower threshold value use for clipping.  
**upper** [float] Upper threshold value use for clipping.

### Examples

```
>>> from scipy.stats import sigmaclip
>>> a = np.concatenate((np.linspace(9.5, 10.5, 31),
... np.linspace(0, 20, 5)))
>>> fact = 1.5
>>> c, low, upp = sigmaclip(a, fact, fact)
>>> c
array([9.96666667, 10. , 10.03333333, 10.])
>>> c.var(), c.std()
(0.000555555555555555165, 0.023570226039551501)
>>> low, c.mean() - fact*c.std(), c.min()
(9.9646446609406727, 9.9646446609406727, 9.9666666666666668)
>>> upp, c.mean() + fact*c.std(), c.max()
(10.035355339059327, 10.035355339059327, 10.033333333333333)
```

```
>>> a = np.concatenate((np.linspace(9.5, 10.5, 11),
... np.linspace(-100, -50, 3)))
>>> c, low, upp = sigmaclip(a, 1.8, 1.8)
>>> (c == np.linspace(9.5, 10.5, 11)).all()
True
```

### scipy.stats.trimboth

`scipy.stats.trimboth(a, proportiontocut, axis=0)`

Slices off a proportion of items from both ends of an array.

Slices off the passed proportion of items from both ends of the passed array (i.e., with *proportiontocut* = 0.1, slices leftmost 10% **and** rightmost 10% of scores). The trimmed values are the lowest and highest ones. Slices off less if proportion results in a non-integer slice index (i.e., conservatively slices off ‘*proportiontocut*’).

#### Parameters

**a** [array\_like] Data to trim.  
**proportiontocut** [float] Proportion (in range 0-1) of total data set to trim of each end.  
**axis** [int or None, optional] Axis along which to trim data. Default is 0. If None, compute over the whole array *a*.

#### Returns

**out** [ndarray] Trimmed version of array *a*. The order of the trimmed content is undefined.

See also:

`trim_mean`

### Examples

```
>>> from scipy import stats
>>> a = np.arange(20)
>>> b = stats.trimboth(a, 0.1)
>>> b.shape
(16,)
```

## scipy.stats.trim1

`scipy.stats.trim1(a, proportiontocut, tail='right', axis=0)`

Slices off a proportion from ONE end of the passed array distribution.

If *proportiontocut* = 0.1, slices off 'leftmost' or 'rightmost' 10% of scores. The lowest or highest values are trimmed (depending on the tail). Slices off less if proportion results in a non-integer slice index (i.e., conservatively slices off *proportiontocut* ).

### Parameters

**a** [array\_like] Input array

**proportiontocut** [float] Fraction to cut off of 'left' or 'right' of distribution

**tail** [{'left', 'right'}, optional] Defaults to 'right'.

**axis** [int or None, optional] Axis along which to trim data. Default is 0. If None, compute over the whole array *a*.

### Returns

**trim1** [ndarray] Trimmed version of array *a*. The order of the trimmed content is undefined.

## scipy.stats.zmap

`scipy.stats.zmap(scores, compare, axis=0, ddof=0)`

Calculate the relative z-scores.

Return an array of z-scores, i.e., scores that are standardized to zero mean and unit variance, where mean and variance are calculated from the comparison array.

### Parameters

**scores** [array\_like] The input for which z-scores are calculated.

**compare** [array\_like] The input from which the mean and standard deviation of the normalization are taken; assumed to have the same dimension as *scores*.

**axis** [int or None, optional] Axis over which mean and variance of *compare* are calculated. Default is 0. If None, compute over the whole array *scores*.

**ddof** [int, optional] Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

### Returns

**zscore** [array\_like] Z-scores, in the same shape as *scores*.

## Notes

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses *asanyarray* instead of *asarray* for parameters).

## Examples

```
>>> from scipy.stats import zmap
>>> a = [0.5, 2.0, 2.5, 3]
>>> b = [0, 1, 2, 3, 4]
>>> zmap(a, b)
array([-1.06066017, 0. , 0.35355339, 0.70710678])
```

## scipy.stats.zscore

`scipy.stats.zscore` (*a*, *axis=0*, *ddof=0*)

Calculate the z score of each value in the sample, relative to the sample mean and standard deviation.

### Parameters

- a** [array\_like] An array like object containing the sample data.
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- ddof** [int, optional] Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

### Returns

- zscore** [array\_like] The z-scores, standardized by mean and standard deviation of input array *a*.

## Notes

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses *asanyarray* instead of *asarray* for parameters).

## Examples

```
>>> a = np.array([0.7972, 0.0767, 0.4383, 0.7866, 0.8091,
... 0.1954, 0.6307, 0.6599, 0.1065, 0.0508])
>>> from scipy import stats
>>> stats.zscore(a)
array([1.1273, -1.247 , -0.0552, 1.0923, 1.1664, -0.8559, 0.5786,
 0.6748, -1.1488, -1.3324])
```

Computing along a specified axis, using n-1 degrees of freedom (*ddof=1*) to calculate the standard deviation:

```
>>> b = np.array([[0.3148, 0.0478, 0.6243, 0.4608],
... [0.7149, 0.0775, 0.6072, 0.9656],
... [0.6341, 0.1403, 0.9759, 0.4064],
... [0.5918, 0.6948, 0.904 , 0.3721],
... [0.0921, 0.2481, 0.1188, 0.1366]])
>>> stats.zscore(b, axis=1, ddof=1)
array([[-0.19264823, -1.28415119, 1.07259584, 0.40420358],
 [0.33048416, -1.37380874, 0.04251374, 1.00081084],
 [0.26796377, -1.12598418, 1.23283094, -0.37481053],
 [-0.22095197, 0.24468594, 1.19042819, -1.21416216],
 [-0.82780366, 1.4457416 , -0.43867764, -0.1792603]])
```

## 6.28.12 Statistical distances

<code>wasserstein_distance(u_values, v_values[, ...])</code>	Compute the first Wasserstein distance between two 1D distributions.
<code>energy_distance(u_values, v_values[, ...])</code>	Compute the energy distance between two 1D distributions.

### scipy.stats.wasserstein\_distance

`scipy.stats.wasserstein_distance(u_values, v_values, u_weights=None, v_weights=None)`

Compute the first Wasserstein distance between two 1D distributions.

This distance is also known as the earth mover’s distance, since it can be seen as the minimum amount of “work” required to transform  $u$  into  $v$ , where “work” is measured as the amount of distribution weight that must be moved, multiplied by the distance it has to be moved.

New in version 1.0.0.

#### Parameters

##### **u\_values, v\_values**

[array\_like] Values observed in the (empirical) distribution.

##### **u\_weights, v\_weights**

[array\_like, optional] Weight for each value. If unspecified, each value is assigned the same weight.  $u\_weights$  (resp.  $v\_weights$ ) must have the same length as  $u\_values$  (resp.  $v\_values$ ). If the weight sum differs from 1, it must still be positive and finite so that the weights can be normalized to sum to 1.

#### Returns

**distance** [float] The computed distance between the distributions.

#### Notes

The first Wasserstein distance between the distributions  $u$  and  $v$  is:

$$l_1(u, v) = \inf_{\pi \in \Gamma(u, v)} \int_{\mathbb{R} \times \mathbb{R}} |x - y| d\pi(x, y)$$

where  $\Gamma(u, v)$  is the set of (probability) distributions on  $\mathbb{R} \times \mathbb{R}$  whose marginals are  $u$  and  $v$  on the first and second factors respectively.

If  $U$  and  $V$  are the respective CDFs of  $u$  and  $v$ , this distance also equals to:

$$l_1(u, v) = \int_{-\infty}^{+\infty} |U - V|$$

See [2] for a proof of the equivalence of both definitions.

The input distributions can be empirical, therefore coming from samples whose values are effectively inputs of the function, or they can be seen as generalized functions, in which case they are weighted sums of Dirac delta functions located at the specified values.

#### References

[1], [2]

## Examples

```
>>> from scipy.stats import wasserstein_distance
>>> wasserstein_distance([0, 1, 3], [5, 6, 8])
5.0
>>> wasserstein_distance([0, 1], [0, 1], [3, 1], [2, 2])
0.25
>>> wasserstein_distance([3.4, 3.9, 7.5, 7.8], [4.5, 1.4],
... [1.4, 0.9, 3.1, 7.2], [3.2, 3.5])
4.0781331438047861
```

## scipy.stats.energy\_distance

`scipy.stats.energy_distance` (*u\_values*, *v\_values*, *u\_weights=None*, *v\_weights=None*)

Compute the energy distance between two 1D distributions.

New in version 1.0.0.

### Parameters

#### **u\_values, v\_values**

[array\_like] Values observed in the (empirical) distribution.

#### **u\_weights, v\_weights**

[array\_like, optional] Weight for each value. If unspecified, each value is assigned the same weight. *u\_weights* (resp. *v\_weights*) must have the same length as *u\_values* (resp. *v\_values*). If the weight sum differs from 1, it must still be positive and finite so that the weights can be normalized to sum to 1.

### Returns

**distance** [float] The computed distance between the distributions.

## Notes

The energy distance between two distributions  $u$  and  $v$ , whose respective CDFs are  $U$  and  $V$ , equals to:

$$D(u, v) = (2\mathbb{E}|X - Y| - \mathbb{E}|X - X'| - \mathbb{E}|Y - Y'|)^{1/2}$$

where  $X$  and  $X'$  (resp.  $Y$  and  $Y'$ ) are independent random variables whose probability distribution is  $u$  (resp.  $v$ ).

As shown in [2], for one-dimensional real-valued variables, the energy distance is linked to the non-distribution-free version of the Cramer-von Mises distance:

$$D(u, v) = \sqrt{2}l_2(u, v) = \left(2 \int_{-\infty}^{+\infty} (U - V)^2\right)^{1/2}$$

Note that the common Cramer-von Mises criterion uses the distribution-free version of the distance. See [2] (section 2), for more details about both versions of the distance.

The input distributions can be empirical, therefore coming from samples whose values are effectively inputs of the function, or they can be seen as generalized functions, in which case they are weighted sums of Dirac delta functions located at the specified values.

## 6.28.13 Random variate generation

---

<code>rvs_ratio_uniforms(pdf, umax, vmin, vmax[, ...])</code>	Generate random samples from a probability density function using the ratio-of-uniforms method.
---------------------------------------------------------------	-------------------------------------------------------------------------------------------------

---

**scipy.stats.rvs\_ratio\_uniforms**

`scipy.stats.rvs_ratio_uniforms(pdf, umax, vmin, vmax, size=1, c=0, random_state=None)`  
 Generate random samples from a probability density function using the ratio-of-uniforms method.

**Parameters**

<b>pdf</b>	[callable] A function with signature $pdf(x)$ that is the probability density function of the distribution.
<b>umax</b>	[float] The upper bound of the bounding rectangle in the $u$ -direction.
<b>vmin</b>	[float] The lower bound of the bounding rectangle in the $v$ -direction.
<b>vmax</b>	[float] The upper bound of the bounding rectangle in the $v$ -direction.
<b>size</b>	[int or tuple of ints, optional] Defining number of random variates (default is 1).
<b>c</b>	[float, optional.] Shift parameter of ratio-of-uniforms method, see Notes. Default is 0.
<b>random_state</b>	[int or <code>np.random.RandomState</code> instance, optional] If already a <code>RandomState</code> instance, use it. If <code>seed</code> is an int, return a new <code>RandomState</code> instance seeded with <code>seed</code> . If <code>None</code> , use <code>np.random.RandomState</code> . Default is <code>None</code> .

**Returns**

<b>rvs</b>	[ndarray] The random variates distributed according to the probability distribution defined by the pdf.
------------	---------------------------------------------------------------------------------------------------------

**Notes**

Given a univariate probability density function  $pdf$  and a constant  $c$ , define the set  $A = \{(u, v) : 0 < u \leq \sqrt{pdf(v/u + c)}\}$ . If  $(U, V)$  is a random vector uniformly distributed over  $A$ , then  $V/U + c$  follows a distribution according to  $pdf$ .

The above result (see [1], [2]) can be used to sample random variables using only the pdf, i.e. no inversion of the cdf is required. Typical choices of  $c$  are zero or the mode of  $pdf$ . The set  $A$  is a subset of the rectangle  $R = [0, umax] \times [vmin, vmax]$  where

- $umax = \sup \sqrt{pdf(x)}$
- $vmin = \inf (x - c) \sqrt{pdf(x)}$

$$\bullet \text{vmax} = \sup (x - c) \sqrt{\text{pdf}(x)}$$

In particular, these values are finite if *pdf* is bounded and  $x^2 * \text{pdf}(x)$  is bounded (i.e. subquadratic tails). One can generate  $(U, V)$  uniformly on  $R$  and return  $V/U + c$  if  $(U, V)$  are also in  $A$  which can be directly verified.

Intuitively, the method works well if  $A$  fills up most of the enclosing rectangle such that the probability is high that  $(U, V)$  lies in  $A$  whenever it lies in  $R$  as the number of required iterations becomes too large otherwise. To be more precise, note that the expected number of iterations to draw  $(U, V)$  uniformly distributed on  $R$  such that  $(U, V)$  is also in  $A$  is given by the ratio  $\text{area}(R) / \text{area}(A) = 2 * \text{umax} * (\text{vmax} - \text{vmin})$ , using the fact that the area of  $A$  is equal to  $1/2$  (Theorem 7.1 in [1]). A warning is displayed if this ratio is larger than 20. Moreover, if the sampling fails to generate a single random variate after 50000 iterations (i.e. not a single draw is in  $A$ ), an exception is raised.

If the bounding rectangle is not correctly specified (i.e. if it does not contain  $A$ ), the algorithm samples from a distribution different from the one given by *pdf*. It is therefore recommended to perform a test such as *kstest* as a check.

## References

[1], [2], [3]

## Examples

```
>>> from scipy import stats
```

Simulate normally distributed random variables. It is easy to compute the bounding rectangle explicitly in that case.

```
>>> f = stats.norm.pdf
>>> v_bound = np.sqrt(f(np.sqrt(2))) * np.sqrt(2)
>>> umax, vmin, vmax = np.sqrt(f(0)), -v_bound, v_bound
>>> np.random.seed(12345)
>>> rvs = stats.rvs_ratio_uniforms(f, umax, vmin, vmax, size=2500)
```

The K-S test confirms that the random variates are indeed normally distributed (normality is not rejected at 5% significance level):

```
>>> stats.kstest(rvs, 'norm')[1]
0.3420173467307603
```

The exponential distribution provides another example where the bounding rectangle can be determined explicitly.

```
>>> np.random.seed(12345)
>>> rvs = stats.rvs_ratio_uniforms(lambda x: np.exp(-x), umax=1,
... vmin=0, vmax=2*np.exp(-1), size=1000)
>>> stats.kstest(rvs, 'expon')[1]
0.928454552559516
```

Sometimes it can be helpful to use a non-zero shift parameter  $c$ , see e.g. [2] above in the case of the generalized inverse Gaussian distribution.

### 6.28.14 Circular statistical functions

<code>circmean(samples[, high, low, axis])</code>	Compute the circular mean for samples in a range.
<code>circvar(samples[, high, low, axis])</code>	Compute the circular variance for samples assumed to be in a range
<code>circstd(samples[, high, low, axis])</code>	Compute the circular standard deviation for samples assumed to be in the range [low to high].

### scipy.stats.circmean

`scipy.stats.circmean` (*samples*, *high*=6.283185307179586, *low*=0, *axis*=None)

Compute the circular mean for samples in a range.

#### Parameters

<b>samples</b>	[array_like] Input array.
<b>high</b>	[float or int, optional] High boundary for circular mean range. Default is $2\pi$ .
<b>low</b>	[float or int, optional] Low boundary for circular mean range. Default is 0.
<b>axis</b>	[int, optional] Axis along which means are computed. The default is to compute the mean of the flattened array.

#### Returns

**circmean** [float] Circular mean.

### Examples

```
>>> from scipy.stats import circmean
>>> circmean([0.1, 2*np.pi+0.2, 6*np.pi+0.3])
0.2
```

```
>>> from scipy.stats import circmean
>>> circmean([0.2, 1.4, 2.6], high = 1, low = 0)
0.4
```

### scipy.stats.circvar

`scipy.stats.circvar` (*samples*, *high*=6.283185307179586, *low*=0, *axis*=None)

Compute the circular variance for samples assumed to be in a range

#### Parameters

<b>samples</b>	[array_like] Input array.
<b>low</b>	[float or int, optional] Low boundary for circular variance range. Default is 0.
<b>high</b>	[float or int, optional] High boundary for circular variance range. Default is $2\pi$ .
<b>axis</b>	[int, optional] Axis along which variances are computed. The default is to compute the variance of the flattened array.

#### Returns

**circvar** [float] Circular variance.

### Notes

This uses a definition of circular variance that in the limit of small angles returns a number close to the ‘linear’ variance.

## Examples

```
>>> from scipy.stats import circvar
>>> circvar([0, 2*np.pi/3, 5*np.pi/3])
2.19722457734
```

## scipy.stats.circstd

`scipy.stats.circstd` (*samples*, *high*=6.283185307179586, *low*=0, *axis*=None)

Compute the circular standard deviation for samples assumed to be in the range [low to high].

### Parameters

**samples** [array\_like] Input array.  
**low** [float or int, optional] Low boundary for circular standard deviation range. Default is 0.  
**high** [float or int, optional] High boundary for circular standard deviation range. Default is  $2\pi$ .  
**axis** [int, optional] Axis along which standard deviations are computed. The default is to compute the standard deviation of the flattened array.

### Returns

**circstd** [float] Circular standard deviation.

## Notes

This uses a definition of circular standard deviation that in the limit of small angles returns a number close to the 'linear' standard deviation.

## Examples

```
>>> from scipy.stats import circstd
>>> circstd([0, 0.1*np.pi/2, 0.001*np.pi, 0.03*np.pi/2])
0.063564063306
```

## 6.28.15 Contingency table functions

<code>chi2_contingency</code> ( <i>observed</i> [, <i>correction</i> , <i>lambda_</i> ])	Chi-square test of independence of variables in a contingency table.
<code>contingency.expected_freq</code> ( <i>observed</i> )	Compute the expected frequencies from a contingency table.
<code>contingency.margins</code> ( <i>a</i> )	Return a list of the marginal sums of the array <i>a</i> .
<code>fisher_exact</code> ( <i>table</i> [, <i>alternative</i> ])	Performs a Fisher exact test on a 2x2 contingency table.

## scipy.stats.chi2\_contingency

`scipy.stats.chi2_contingency` (*observed*, *correction*=True, *lambda\_*=None)

Chi-square test of independence of variables in a contingency table.

This function computes the chi-square statistic and p-value for the hypothesis test of independence of the observed frequencies in the contingency table [1] *observed*. The expected frequencies are computed based on the marginal

sums under the assumption of independence; see `scipy.stats.contingency.expected_freq`. The number of degrees of freedom is (expressed using numpy functions and attributes):

```
dof = observed.size - sum(observed.shape) + observed.ndim - 1
```

### Parameters

- observed** [array\_like] The contingency table. The table contains the observed frequencies (i.e. number of occurrences) in each category. In the two-dimensional case, the table is often described as an “R x C table”.
- correction** [bool, optional] If True, *and* the degrees of freedom is 1, apply Yates’ correction for continuity. The effect of the correction is to adjust each observed value by 0.5 towards the corresponding expected value.
- lambda\_** [float or str, optional.] By default, the statistic computed in this test is Pearson’s chi-squared statistic [2]. *lambda\_* allows a statistic from the Cressie-Read power divergence family [3] to be used instead. See *power\_divergence* for details.

### Returns

- chi2** [float] The test statistic.
- p** [float] The p-value of the test
- dof** [int] Degrees of freedom
- expected** [ndarray, same shape as *observed*] The expected frequencies, based on the marginal sums of the table.

### See also:

`contingency.expected_freq`, `fisher_exact`, `chisquare`, `power_divergence`

### Notes

An often quoted guideline for the validity of this calculation is that the test should be used only if the observed and expected frequencies in each cell are at least 5.

This is a test for the independence of different categories of a population. The test is only meaningful when the dimension of *observed* is two or more. Applying the test to a one-dimensional table will always result in *expected* equal to *observed* and a chi-square statistic equal to 0.

This function does not handle masked arrays, because the calculation does not make sense with missing values.

Like `stats.chisquare`, this function computes a chi-square statistic; the convenience this function provides is to figure out the expected frequencies and degrees of freedom from the given contingency table. If these were already known, and if the Yates’ correction was not required, one could use `stats.chisquare`. That is, if one calls:

```
chi2, p, dof, ex = chi2_contingency(obs, correction=False)
```

then the following is true:

```
(chi2, p) == stats.chisquare(obs.ravel(), f_exp=ex.ravel(),
 ddof=obs.size - 1 - dof)
```

The *lambda\_* argument was added in version 0.13.0 of scipy.

### References

- [1], [2], [3]

## Examples

A two-way example (2 x 3):

```
>>> from scipy.stats import chi2_contingency
>>> obs = np.array([[10, 10, 20], [20, 20, 20]])
>>> chi2_contingency(obs)
(2.7777777777777777,
 0.24935220877729619,
 2,
 array([[12., 12., 16.],
 [18., 18., 24.]])
```

Perform the test using the log-likelihood ratio (i.e. the “G-test”) instead of Pearson’s chi-squared statistic.

```
>>> g, p, dof, expctd = chi2_contingency(obs, lambda_="log-likelihood")
>>> g, p
(2.7688587616781319, 0.25046668010954165)
```

A four-way example (2 x 2 x 2 x 2):

```
>>> obs = np.array(
... [[[[12, 17],
... [11, 16]],
... [[11, 12],
... [15, 16]]],
... [[23, 15],
... [30, 22]],
... [[14, 17],
... [15, 16]]]])
>>> chi2_contingency(obs)
(8.7584514426741897,
 0.64417725029295503,
 11,
 array([[[[14.15462386, 14.15462386],
 [16.49423111, 16.49423111]],
 [[11.2461395, 11.2461395],
 [13.10500554, 13.10500554]]],
 [[19.5591166, 19.5591166],
 [22.79202844, 22.79202844]],
 [[15.54012004, 15.54012004],
 [18.10873492, 18.10873492]]]])
```

## scipy.stats.contingency.expected\_freq

`scipy.stats.contingency.expected_freq` (*observed*)

Compute the expected frequencies from a contingency table.

Given an n-dimensional contingency table of observed frequencies, compute the expected frequencies for the table based on the marginal sums under the assumption that the groups associated with each dimension are independent.

### Parameters

**observed** [array\_like] The table of observed frequencies. (While this function can handle a 1-D array, that case is trivial. Generally *observed* is at least 2-D.)

**Returns**

**expected** [ndarray of float64] The expected frequencies, based on the marginal sums of the table. Same shape as *observed*.

**Examples**

```
>>> observed = np.array([[10, 10, 20], [20, 20, 20]])
>>> from scipy.stats.contingency import expected_freq
>>> expected_freq(observed)
array([[12., 12., 16.],
 [18., 18., 24.]])
```

**scipy.stats.contingency.margins**

`scipy.stats.contingency.margins` (*a*)

Return a list of the marginal sums of the array *a*.

**Parameters**

**a** [ndarray] The array for which to compute the marginal sums.

**Returns**

**margsums** [list of ndarrays] A list of length *a.ndim*. *margsums[k]* is the result of summing *a* over all axes except *k*; it has the same number of dimensions as *a*, but the length of each axis except axis *k* will be 1.

**Examples**

```
>>> a = np.arange(12).reshape(2, 6)
>>> a
array([[0, 1, 2, 3, 4, 5],
 [6, 7, 8, 9, 10, 11]])
>>> from scipy.stats.contingency import margins
>>> m0, m1 = margins(a)
>>> m0
array([[15],
 [51]])
>>> m1
array([[6, 8, 10, 12, 14, 16]])
```

```
>>> b = np.arange(24).reshape(2, 3, 4)
>>> m0, m1, m2 = margins(b)
>>> m0
array([[[66]],
 [[210]]])
>>> m1
array([[[60],
 [92],
 [124]]])
```

(continues on next page)

(continued from previous page)

```
>>> m2
array([[60, 66, 72, 78]])
```

## scipy.stats.fisher\_exact

`scipy.stats.fisher_exact` (*table*, *alternative='two-sided'*)

Performs a Fisher exact test on a 2x2 contingency table.

### Parameters

**table** [array\_like of ints] A 2x2 contingency table. Elements should be non-negative integers.  
**alternative** [{‘two-sided’, ‘less’, ‘greater’}, optional] Which alternative hypothesis to the null hypothesis the test uses. Default is ‘two-sided’.

### Returns

**oddsratio** [float] This is prior odds ratio and not a posterior estimate.  
**p\_value** [float] P-value, the probability of obtaining a distribution at least as extreme as the one that was actually observed, assuming that the null hypothesis is true.

See also:

### [chi2\\_contingency](#)

Chi-square test of independence of variables in a contingency table.

## Notes

The calculated odds ratio is different from the one R uses. This scipy implementation returns the (more common) “unconditional Maximum Likelihood Estimate”, while R uses the “conditional Maximum Likelihood Estimate”.

For tables with large numbers, the (inexact) chi-square test implemented in the function `chi2_contingency` can also be used.

## Examples

Say we spend a few days counting whales and sharks in the Atlantic and Indian oceans. In the Atlantic ocean we find 8 whales and 1 shark, in the Indian ocean 2 whales and 5 sharks. Then our contingency table is:

	Atlantic	Indian
whales	8	2
sharks	1	5

We use this table to find the p-value:

```
>>> import scipy.stats as stats
>>> oddsratio, pvalue = stats.fisher_exact([[8, 2], [1, 5]])
>>> pvalue
0.0349...
```

The probability that we would observe this or an even more imbalanced ratio by chance is about 3.5%. A commonly used significance level is 5%—if we adopt that, we can therefore conclude that our observed imbalance is statistically significant; whales prefer the Atlantic while sharks prefer the Indian ocean.

## 6.28.16 Plot-tests

<code>ppcc_max(x[, brack, dist])</code>	Calculate the shape parameter that maximizes the PPCC
<code>ppcc_plot(x, a, b[, dist, plot, N])</code>	Calculate and optionally plot probability plot correlation coefficient.
<code>probplot(x[, sparams, dist, fit, plot, rvalue])</code>	Calculate quantiles for a probability plot, and optionally show the plot.
<code>boxcox_normplot(x, la, lb[, plot, N])</code>	Compute parameters for a Box-Cox normality plot, optionally show it.
<code>yeojohnson_normplot(x, la, lb[, plot, N])</code>	Compute parameters for a Yeo-Johnson normality plot, optionally show it.

### scipy.stats.ppcc\_max

`scipy.stats.ppcc_max(x, brack=(0.0, 1.0), dist='tukeylambda')`

Calculate the shape parameter that maximizes the PPCC

The probability plot correlation coefficient (PPCC) plot can be used to determine the optimal shape parameter for a one-parameter family of distributions. `ppcc_max` returns the shape parameter that would maximize the probability plot correlation coefficient for the given data to a one-parameter family of distributions.

#### Parameters

- x** [array\_like] Input array.
- brack** [tuple, optional] Triple (a,b,c) where (a<b<c). If bracket consists of two numbers (a, c) then they are assumed to be a starting interval for a downhill bracket search (see `scipy.optimize.brent`).
- dist** [str or stats.distributions instance, optional] Distribution or distribution function name. Objects that look enough like a stats.distributions instance (i.e. they have a `ppf` method) are also accepted. The default is `'tukeylambda'`.

#### Returns

- shape\_value** [float] The shape parameter at which the probability plot correlation coefficient reaches its max value.

#### See also:

`ppcc_plot`, `probplot`, `boxcox`

#### Notes

The `brack` keyword serves as a starting point which is useful in corner cases. One can use a plot to obtain a rough visual estimate of the location for the maximum to start the search near it.

#### References

[1], [2]

#### Examples

First we generate some random data from a Tukey-Lambda distribution, with shape parameter -0.7:

```
>>> from scipy import stats
>>> x = stats.tukeylambd.rvs(-0.7, loc=2, scale=0.5, size=10000,
... random_state=1234567) + 1e4
```

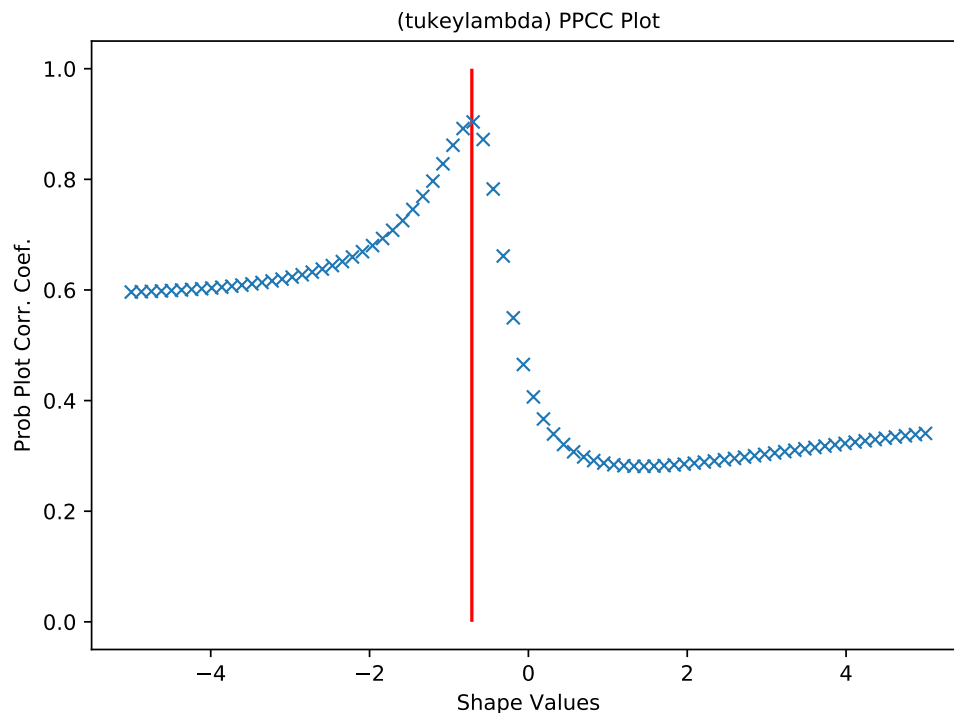

Now we explore this data with a PPCC plot as well as the related probability plot and Box-Cox normplot. A red line is drawn where we expect the PPCC value to be maximal (at the shape parameter -0.7 used above):

```
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure(figsize=(8, 6))
>>> ax = fig.add_subplot(111)
>>> res = stats.ppcc_plot(x, -5, 5, plot=ax)
```

We calculate the value where the shape should reach its maximum and a red line is drawn there. The line should coincide with the highest point in the ppcc\_plot.

```
>>> max = stats.ppcc_max(x)
>>> ax.vlines(max, 0, 1, colors='r', label='Expected shape value')
```

```
>>> plt.show()
```

## scipy.stats.ppcc\_plot

`scipy.stats.ppcc_plot(x, a, b, dist='tukeylambda', plot=None, N=80)`

Calculate and optionally plot probability plot correlation coefficient.

The probability plot correlation coefficient (PPCC) plot can be used to determine the optimal shape parameter for a one-parameter family of distributions. It cannot be used for distributions without shape parameters (like the normal distribution) or with multiple shape parameters.

By default a Tukey-Lambda distribution (`stats.tukeylambda`) is used. A Tukey-Lambda PPCC plot interpolates from long-tailed to short-tailed distributions via an approximately normal one, and is therefore particularly useful in practice.

### Parameters

<b>x</b>	[array_like] Input array.
<b>a, b: scalar</b>	Lower and upper bounds of the shape parameter to use.
<b>dist</b>	[str or stats.distributions instance, optional] Distribution or distribution function name. Objects that look enough like a stats.distributions instance (i.e. they have a <code>ppf</code> method) are also accepted. The default is <code>'tukeylambda'</code> .
<b>plot</b>	[object, optional] If given, plots PPCC against the shape parameter. <code>plot</code> is an object that has to have methods “plot” and “text”. The <code>matplotlib.pyplot</code> module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is <code>None</code> , which means that no plot is created.
<b>N</b>	[int, optional] Number of points on the horizontal axis (equally distributed from <code>a</code> to <code>b</code> ).

### Returns

<b>svals</b>	[ndarray] The shape values for which <code>ppcc</code> was calculated.
<b>ppcc</b>	[ndarray] The calculated probability plot correlation coefficient values.

### See also:

[`ppcc\_max`](#), [`probplot`](#), [`boxcox\_normplot`](#), [`tukeylambda`](#)

## References

J.J. Filliben, “The Probability Plot Correlation Coefficient Test for Normality”, *Technometrics*, Vol. 17, pp. 111-117, 1975.

## Examples

First we generate some random data from a Tukey-Lambda distribution, with shape parameter -0.7:

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> np.random.seed(1234567)
>>> x = stats.tukeylambda.rvs(-0.7, loc=2, scale=0.5, size=10000) + 1e4
```

Now we explore this data with a PPCC plot as well as the related probability plot and Box-Cox normplot. A red line is drawn where we expect the PPCC value to be maximal (at the shape parameter -0.7 used above):

```

>>> fig = plt.figure(figsize=(12, 4))
>>> ax1 = fig.add_subplot(131)
>>> ax2 = fig.add_subplot(132)
>>> ax3 = fig.add_subplot(133)
>>> res = stats.probplot(x, plot=ax1)
>>> res = stats.boxcox_normplot(x, -5, 5, plot=ax2)
>>> res = stats.ppcc_plot(x, -5, 5, plot=ax3)
>>> ax3.vlines(-0.7, 0, 1, colors='r', label='Expected shape value')
>>> plt.show()

```

## scipy.stats.probplot

`scipy.stats.probplot(x, sparams=(), dist='norm', fit=True, plot=None, rvalue=False)`

Calculate quantiles for a probability plot, and optionally show the plot.

Generates a probability plot of sample data against the quantiles of a specified theoretical distribution (the normal distribution by default). `probplot` optionally calculates a best-fit line for the data and plots the results using Matplotlib or a given plot function.

### Parameters

- x** [array\_like] Sample/response data from which `probplot` creates the plot.
- sparams** [tuple, optional] Distribution-specific shape parameters (shape parameters plus location and scale).
- dist** [str or stats.distributions instance, optional] Distribution or distribution function name. The default is 'norm' for a normal probability plot. Objects that look enough like a `stats.distributions` instance (i.e. they have a `ppf` method) are also accepted.
- fit** [bool, optional] Fit a least-squares regression (best-fit) line to the sample data if True (default).
- plot** [object, optional] If given, plots the quantiles and least squares fit. `plot` is an object that has to have methods "plot" and "text". The `matplotlib.pyplot` module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is None, which means that no plot is created.

### Returns

- (osm, osr)** [tuple of ndarrays] Tuple of theoretical quantiles (`osm`, or order statistic medians) and ordered responses (`osr`). `osr` is simply sorted input `x`. For details on how `osm` is calculated see the Notes section.

**(slope, intercept, r)**

[tuple of floats, optional] Tuple containing the result of the least-squares fit, if that is performed by `probplot`. `r` is the square root of the coefficient of determination. If `fit=False` and `plot=None`, this tuple is not returned.

**Notes**

Even if `plot` is given, the figure is not shown or saved by `probplot`; `plt.show()` or `plt.savefig('filename.png')` should be used after calling `probplot`.

`probplot` generates a probability plot, which should not be confused with a Q-Q or a P-P plot. Statsmodels has more extensive functionality of this type, see `statsmodels.api.ProbPlot`.

The formula used for the theoretical quantiles (horizontal axis of the probability plot) is Filliben's estimate:

```
quantiles = dist.ppf(val), for
 0.5**(1/n), for i = n
 val = (i - 0.3175) / (n + 0.365), for i = 2, ..., n-1
 1 - 0.5**(1/n), for i = 1
```

where `i` indicates the `i`-th ordered value and `n` is the total number of values.

**Examples**

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> nsample = 100
>>> np.random.seed(7654321)
```

A t distribution with small degrees of freedom:

```
>>> ax1 = plt.subplot(221)
>>> x = stats.t.rvs(3, size=nsample)
>>> res = stats.probplot(x, plot=plt)
```

A t distribution with larger degrees of freedom:

```
>>> ax2 = plt.subplot(222)
>>> x = stats.t.rvs(25, size=nsample)
>>> res = stats.probplot(x, plot=plt)
```

A mixture of two normal distributions with broadcasting:

```
>>> ax3 = plt.subplot(223)
>>> x = stats.norm.rvs(loc=[0,5], scale=[1,1.5],
... size=(nsample//2,2)).ravel()
>>> res = stats.probplot(x, plot=plt)
```

A standard normal distribution:

```
>>> ax4 = plt.subplot(224)
>>> x = stats.norm.rvs(loc=0, scale=1, size=nsample)
>>> res = stats.probplot(x, plot=plt)
```

Produce a new figure with a loggamma distribution, using the `dist` and `sparams` keywords:

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> x = stats.loggamma.rvs(c=2.5, size=500)
>>> res = stats.probplot(x, dist=stats.loggamma, sparams=(2.5,), plot=ax)
>>> ax.set_title("Probplot for loggamma dist with shape parameter 2.5")
```

Show the results with Matplotlib:

```
>>> plt.show()
```

**scipy.stats.boxcox\_normplot**

`scipy.stats.boxcox_normplot(x, la, lb, plot=None, N=80)`

Compute parameters for a Box-Cox normality plot, optionally show it.

A Box-Cox normality plot shows graphically what the best transformation parameter is to use in `boxcox` to obtain a distribution that is close to normal.

**Parameters**

<b>x</b>	[array_like] Input array.
<b>la, lb</b>	[scalar] The lower and upper bounds for the <code>lambda</code> values to pass to <code>boxcox</code> for Box-Cox transformations. These are also the limits of the horizontal axis of the plot if that is generated.
<b>plot</b>	[object, optional] If given, plots the quantiles and least squares fit. <code>plot</code> is an object that has to have methods “plot” and “text”. The <code>matplotlib.pyplot</code> module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is <code>None</code> , which means that no plot is created.
<b>N</b>	[int, optional] Number of points on the horizontal axis (equally distributed from <code>la</code> to <code>lb</code> ).

**Returns**

<b>lmbdas</b>	[ndarray] The <code>lambda</code> values for which a Box-Cox transform was done.
<b>ppcc</b>	[ndarray] Probability Plot Correlation Coefficient, as obtained from <code>probplot</code> when fitting the Box-Cox transformed input <code>x</code> against a normal distribution.

**See also:**

`probplot`, `boxcox`, `boxcox_normmax`, `boxcox_llf`, `ppcc_max`

**Notes**

Even if `plot` is given, the figure is not shown or saved by `boxcox_normplot`; `plt.show()` or `plt.savefig('filename.png')` should be used after calling `probplot`.

**Examples**

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

Generate some non-normally distributed data, and create a Box-Cox plot:

```
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.boxcox_normplot(x, -20, 20, plot=ax)
```

Determine and plot the optimal `lambda` to transform `x` and plot it in the same plot:

```
>>> _, maxlog = stats.boxcox(x)
>>> ax.axvline(maxlog, color='r')
```

```
>>> plt.show()
```

### scipy.stats.yeojohnson\_normplot

`scipy.stats.yeojohnson_normplot` (*x*, *la*, *lb*, *plot=None*, *N=80*)

Compute parameters for a Yeo-Johnson normality plot, optionally show it.

A Yeo-Johnson normality plot shows graphically what the best transformation parameter is to use in `yeojohnson` to obtain a distribution that is close to normal.

#### Parameters

- x** [array\_like] Input array.
- la, lb** [scalar] The lower and upper bounds for the `lambda` values to pass to `yeojohnson` for Yeo-Johnson transformations. These are also the limits of the horizontal axis of the plot if that is generated.
- plot** [object, optional] If given, plots the quantiles and least squares fit. *plot* is an object that has to have methods “plot” and “text”. The `matplotlib.pyplot` module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is None, which means that no plot is created.
- N** [int, optional] Number of points on the horizontal axis (equally distributed from *la* to *lb*).

#### Returns

- lmbdas** [ndarray] The `lambda` values for which a Yeo-Johnson transform was done.
- ppcc** [ndarray] Probability Plot Correlation Coefficient, as obtained from `probplot` when fitting the Box-Cox transformed input *x* against a normal distribution.

#### See also:

`probplot`, `yeojohnson`, `yeojohnson_normmax`, `yeojohnson_llf`, `ppcc_max`

#### Notes

Even if *plot* is given, the figure is not shown or saved by `boxcox_normplot`; `plt.show()` or `plt.savefig('figname.png')` should be used after calling `probplot`.

New in version 1.2.0.

## Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

Generate some non-normally distributed data, and create a Yeo-Johnson plot:

```
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.yeojohnson_normplot(x, -20, 20, plot=ax)
```

Determine and plot the optimal lambda to transform x and plot it in the same plot:

```
>>> _, maxlog = stats.yeojohnson(x)
>>> ax.axvline(maxlog, color='r')
```

```
>>> plt.show()
```

## 6.28.17 Masked statistics functions

### Statistical functions for masked arrays (`scipy.stats.mstats`)

This module contains a large number of statistical functions that can be used with masked arrays.

Most of these functions are similar to those in `scipy.stats` but might have small differences in the API or in the algorithm used. Since this is a relatively new package, some API changes are still possible.

### Summary statistics

<code>describe(a[, axis, ddof, bias])</code>	Computes several descriptive statistics of the passed array.
<code>gmean(a[, axis, dtype])</code>	Compute the geometric mean along the specified axis.
<code>hmean(a[, axis, dtype])</code>	Calculate the harmonic mean along the specified axis.
<code>kurtosis(a[, axis, fisher, bias])</code>	Computes the kurtosis (Fisher or Pearson) of a dataset.
<code>mode(a[, axis])</code>	Returns an array of the modal (most common) value in the passed array.
<code>mquantiles(a[, prob, alphap, betap, axis, limit])</code>	Computes empirical quantiles for a data array.
<code>hdmedian(data[, axis, var])</code>	Returns the Harrell-Davis estimate of the median along the given axis.
<code>hdquantiles(data[, prob, axis, var])</code>	Computes quantile estimates with the Harrell-Davis method.
<code>hdquantiles_sd(data[, prob, axis])</code>	The standard error of the Harrell-Davis quantile estimates by jackknife.
<code>idealfourths(data[, axis])</code>	Returns an estimate of the lower and upper quartiles.
<code>plotting_positions(data[, alpha, beta])</code>	Returns plotting positions (or empirical percentile points) for the data.
<code>meppf(data[, alpha, beta])</code>	Returns plotting positions (or empirical percentile points) for the data.
<code>moment(a[, moment, axis])</code>	Calculates the nth moment about the mean for a sample.
<code>skew(a[, axis, bias])</code>	Computes the skewness of a data set.
<code>tmean(a[, limits, inclusive, axis])</code>	Compute the trimmed mean.
<code>tvar(a[, limits, inclusive, axis, ddof])</code>	Compute the trimmed variance
<code>tmin(a[, lowerlimit, axis, inclusive])</code>	Compute the trimmed minimum
<code>tmax(a[, upperlimit, axis, inclusive])</code>	Compute the trimmed maximum
<code>tsem(a[, limits, inclusive, axis, ddof])</code>	Compute the trimmed standard error of the mean.
<code>variation(a[, axis])</code>	Computes the coefficient of variation, the ratio of the biased standard deviation to the mean.
<code>find_repeats(arr)</code>	Find repeats in arr and return a tuple (repeats, repeat_count).
<code>sem(a[, axis, ddof])</code>	Calculates the standard error of the mean of the input array.
<code>trimmed_mean(a[, limits, inclusive, ...])</code>	
<code>trimmed_mean_ci(data[, limits, inclusive, ...])</code>	Selected confidence interval of the trimmed mean along the given axis.
<code>trimmed_std(a[, limits, inclusive, ...])</code>	
<code>trimmed_var(a[, limits, inclusive, ...])</code>	

### scipy.stats.mstats.describe

`scipy.stats.mstats.describe(a, axis=0, ddof=0, bias=True)`

Computes several descriptive statistics of the passed array.

#### Parameters

<b>a</b>	[array_like] Data array
<b>axis</b>	[int or None, optional] Axis along which to calculate statistics. Default 0. If None, compute over the whole array <i>a</i> .
<b>ddof</b>	[int, optional] degree of freedom (default 0); note that default ddof is different from the same routine in <code>stats.describe</code>
<b>bias</b>	[bool, optional] If False, then the skewness and kurtosis calculations are corrected for statistical bias.

**Returns**

**nobs** [int] (size of the data (discarding missing values))  
**minmax** [(int, int)] min, max  
**mean** [float] arithmetic mean  
**variance** [float] unbiased variance  
**skewness** [float] biased skewness  
**kurtosis** [float] biased kurtosis

**Examples**

```
>>> from scipy.stats.mstats import describe
>>> ma = np.ma.array(range(6), mask=[0, 0, 0, 1, 1, 1])
>>> describe(ma)
DescribeResult (nobs=3, minmax=(masked_array(data=0,
 mask=False,
 fill_value=999999), masked_array(data=2,
 mask=False,
 fill_value=999999)), mean=1.0, variance=0.6666666666666666,
 skewness=masked_array(data=0., mask=False, fill_value=1e+20),
 kurtosis=-1.5)
```

**scipy.stats.mstats.gmean**

scipy.stats.mstats.gmean(a, axis=0, dtype=None)

Compute the geometric mean along the specified axis.

Return the geometric average of the array elements. That is: n-th root of (x1 \* x2 \* ... \* xn)

**Parameters**

**a** [array\_like] Input array or object that can be converted to an array.  
**axis** [int or None, optional] Axis along which the geometric mean is computed. Default is 0. If None, compute over the whole array a.  
**dtype** [dtype, optional] Type of the returned array and of the accumulator in which the elements are summed. If dtype is not specified, it defaults to the dtype of a, unless a has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

**Returns**

**gmean** [ndarray] see dtype parameter above

See also:

**numpy.mean**

Arithmetic average

**numpy.average**

Weighted average

**hmean**

Harmonic mean

## Notes

The geometric average is computed over a single dimension of the input array, `axis=0` by default, or all values in the array if `axis=None`. `float64` intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity because masked arrays automatically mask any non-finite values.

## Examples

```
>>> from scipy.stats import gmean
>>> gmean([1, 4])
2.0
>>> gmean([1, 2, 3, 4, 5, 6, 7])
3.3800151591412964
```

## `scipy.stats.mstats.hmean`

`scipy.stats.mstats.hmean(a, axis=0, dtype=None)`

Calculate the harmonic mean along the specified axis.

That is:  $n / (1/x_1 + 1/x_2 + \dots + 1/x_n)$

### Parameters

- a** [array\_like] Input array, masked array or object that can be converted to an array.
- axis** [int or None, optional] Axis along which the harmonic mean is computed. Default is 0. If None, compute over the whole array *a*.
- dtype** [dtype, optional] Type of the returned array and of the accumulator in which the elements are summed. If *dtype* is not specified, it defaults to the dtype of *a*, unless *a* has an integer *dtype* with a precision less than that of the default platform integer. In that case, the default platform integer is used.

### Returns

- hmean** [ndarray] see *dtype* parameter above

See also:

`numpy.mean`

Arithmetic average

`numpy.average`

Weighted average

`gmean`

Geometric mean

## Notes

The harmonic mean is computed over a single dimension of the input array, `axis=0` by default, or all values in the array if `axis=None`. `float64` intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity.

### Examples

```
>>> from scipy.stats import hmean
>>> hmean([1, 4])
1.6000000000000001
>>> hmean([1, 2, 3, 4, 5, 6, 7])
2.6997245179063363
```

### scipy.stats.mstats.kurtosis

`scipy.stats.mstats.kurtosis` (*a*, *axis=0*, *fisher=True*, *bias=True*)

Computes the kurtosis (Fisher or Pearson) of a dataset.

Kurtosis is the fourth central moment divided by the square of the variance. If Fisher's definition is used, then 3.0 is subtracted from the result to give 0.0 for a normal distribution.

If *bias* is `False` then the kurtosis is calculated using k statistics to eliminate bias coming from biased moment estimators

Use `kurtosistest` to see if result is close enough to normal.

#### Parameters

- a** [array] data for which the kurtosis is calculated
- axis** [int or None, optional] Axis along which the kurtosis is calculated. Default is 0. If None, compute over the whole array *a*.
- fisher** [bool, optional] If True, Fisher's definition is used (normal ==> 0.0). If False, Pearson's definition is used (normal ==> 3.0).
- bias** [bool, optional] If False, then the calculations are corrected for statistical bias.

#### Returns

- kurtosis** [array] The kurtosis of values along an axis. If all values are equal, return -3 for Fisher's definition and 0 for Pearson's definition.

### Notes

For more details about `kurtosis`, see `stats.kurtosis`.

### scipy.stats.mstats.mode

`scipy.stats.mstats.mode` (*a*, *axis=0*)

Returns an array of the modal (most common) value in the passed array.

#### Parameters

- a** [array\_like] n-dimensional array of which to find mode(s).
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.

#### Returns

**mode** [ndarray] Array of modal values.  
**count** [ndarray] Array of counts for each mode.

## Notes

For more details, see `stats.mode`.

## Examples

```
>>> from scipy import stats
>>> from scipy.stats import mstats
>>> m_arr = np.ma.array([1, 1, 0, 0, 0, 0], mask=[0, 0, 1, 1, 1, 0])
>>> stats.mode(m_arr)
ModeResult(mode=array([0]), count=array([4]))
>>> mstats.mode(m_arr)
ModeResult(mode=array([1.]), count=array([2.]))
```

## scipy.stats.mstats.mquantiles

`scipy.stats.mstats.mquantiles(a, prob=[0.25, 0.5, 0.75], alphap=0.4, betap=0.4, axis=None, limit=())`

Computes empirical quantiles for a data array.

Samples quantile are defined by  $Q(p) = (1-\gamma)*x[j] + \gamma*x[j+1]$ , where  $x[j]$  is the  $j$ -th order statistic, and  $\gamma$  is a function of  $j = \text{floor}(n*p + m)$ ,  $m = \text{alphap} + p*(1 - \text{alphap} - \text{betap})$  and  $g = n*p + m - j$ .

Reinterpreting the above equations to compare to **R** lead to the equation:  $p(k) = (k - \text{alphap}) / (n + 1 - \text{alphap} - \text{betap})$

**Typical values of (alphap,betap) are:**

- (0,1):  $p(k) = k/n$ : linear interpolation of cdf (**R** type 4)
- (.5,.5):  $p(k) = (k - 1/2.) / n$ : piecewise linear function (**R** type 5)
- (0,0):  $p(k) = k / (n+1)$ : (**R** type 6)
- (1,1):  $p(k) = (k-1) / (n-1)$ :  $p(k) = \text{mode}[F(x[k])]$ . (**R** type 7, **R** default)
- (1/3,1/3):  $p(k) = (k-1/3) / (n+1/3)$ : Then  $p(k) \sim \text{median}[F(x[k])]$ . The resulting quantile estimates are approximately median-unbiased regardless of the distribution of  $x$ . (**R** type 8)
- (3/8,3/8):  $p(k) = (k-3/8) / (n+1/4)$ : Blom. The resulting quantile estimates are approximately unbiased if  $x$  is normally distributed (**R** type 9)
- (.4,.4): approximately quantile unbiased (Cunnane)
- (.35,.35): APL, used with PWM

### Parameters

**a** [array\_like] Input data, as a sequence or array of dimension at most 2.  
**prob** [array\_like, optional] List of quantiles to compute.  
**alphap** [float, optional] Plotting positions parameter, default is 0.4.  
**betap** [float, optional] Plotting positions parameter, default is 0.4.

**axis** [int, optional] Axis along which to perform the trimming. If None (default), the input array is first flattened.

**limit** [tuple, optional] Tuple of (lower, upper) values. Values of *a* outside this open interval are ignored.

**Returns**

**mquantiles**  
[MaskedArray] An array containing the calculated quantiles.

**Notes**

This formulation is very similar to **R** except the calculation of *m* from `alphap` and `betap`, where in **R** *m* is defined with each type.

**References**

[1], [2]

**Examples**

```
>>> from scipy.stats.mstats import mquantiles
>>> a = np.array([6., 47., 49., 15., 42., 41., 7., 39., 43., 40., 36.])
>>> mquantiles(a)
array([19.2, 40. , 42.8])
```

Using a 2D array, specifying axis and limit.

```
>>> data = np.array([[6., 7., 1.],
... [47., 15., 2.],
... [49., 36., 3.],
... [15., 39., 4.],
... [42., 40., -999.],
... [41., 41., -999.],
... [7., -999., -999.],
... [39., -999., -999.],
... [43., -999., -999.],
... [40., -999., -999.],
... [36., -999., -999.]])
>>> print(mquantiles(data, axis=0, limit=(0, 50)))
[[19.2 14.6 1.45]
 [40. 37.5 2.5]
 [42.8 40.05 3.55]]
```

```
>>> data[:, 2] = -999.
>>> print(mquantiles(data, axis=0, limit=(0, 50)))
[[19.200000000000003 14.6 --]
 [40.0 37.5 --]
 [42.800000000000004 40.05 --]]
```

**scipy.stats.mstats.hdmedian**

`scipy.stats.mstats.hdmedian` (*data*, *axis*=-1, *var*=False)

Returns the Harrell-Davis estimate of the median along the given axis.

**Parameters**

**data** [ndarray] Data array.  
**axis** [int, optional] Axis along which to compute the quantiles. If None, use a flattened array.  
**var** [bool, optional] Whether to return the variance of the estimate.

**Returns**

**hdmedian** [MaskedArray] The median values. If `var=True`, the variance is returned inside the masked array. E.g. for a 1-D array the shape change from (1,) to (2,).

**scipy.stats.mstats.hdquantiles**

`scipy.stats.mstats.hdquantiles` (*data*, *prob*=[0.25, 0.5, 0.75], *axis*=None, *var*=False)

Computes quantile estimates with the Harrell-Davis method.

The quantile estimates are calculated as a weighted linear combination of order statistics.

**Parameters**

**data** [array\_like] Data array.  
**prob** [sequence, optional] Sequence of quantiles to compute.  
**axis** [int or None, optional] Axis along which to compute the quantiles. If None, use a flattened array.  
**var** [bool, optional] Whether to return the variance of the estimate.

**Returns**

**hdquantiles** [MaskedArray] A (p,) array of quantiles (if `var` is False), or a (2,p) array of quantiles and variances (if `var` is True), where `p` is the number of quantiles.

See also:

[`hdquantiles\_sd`](#)

**scipy.stats.mstats.hdquantiles\_sd**

`scipy.stats.mstats.hdquantiles_sd` (*data*, *prob*=[0.25, 0.5, 0.75], *axis*=None)

The standard error of the Harrell-Davis quantile estimates by jackknife.

**Parameters**

**data** [array\_like] Data array.  
**prob** [sequence, optional] Sequence of quantiles to compute.  
**axis** [int, optional] Axis along which to compute the quantiles. If None, use a flattened array.

**Returns**

**hdquantiles\_sd** [MaskedArray] Standard error of the Harrell-Davis quantile estimates.

See also:

[`hdquantiles`](#)

### scipy.stats.mstats.idealfourths

`scipy.stats.mstats.idealfourths` (*data*, *axis=None*)

Returns an estimate of the lower and upper quartiles.

Uses the ideal fourths algorithm.

#### Parameters

**data** [array\_like] Input array.  
**axis** [int, optional] Axis along which the quartiles are estimated. If None, the arrays are flattened.

#### Returns

##### idealfourths

[{list of floats, masked array}] Returns the two internal values that divide *data* into four parts using the ideal fourths algorithm either along the flattened array (if *axis* is None) or along *axis* of *data*.

### scipy.stats.mstats.plotting\_positions

`scipy.stats.mstats.plotting_positions` (*data*, *alpha=0.4*, *beta=0.4*)

Returns plotting positions (or empirical percentile points) for the data.

*Plotting positions are defined as  $(i - \alpha) / (n + 1 - \alpha - \beta)$ , where:*

- *i* is the rank order statistics
- *n* is the number of unmasked values along the given axis
- *alpha* and *beta* are two parameters.

*Typical values for alpha and beta are:*

- (0,1):  $p(k) = k/n$ , linear interpolation of cdf (R, type 4)
- (.5,.5):  $p(k) = (k - 1/2) / n$ , piecewise linear function (R, type 5)
- (0,0):  $p(k) = k / (n + 1)$ , Weibull (R type 6)
- (1,1):  $p(k) = (k - 1) / (n - 1)$ , in this case,  $p(k) = \text{mode}[F(x[k])]$ . That's R default (R type 7)
- (1/3,1/3):  $p(k) = (k - 1/3) / (n + 1/3)$ , then  $p(k) \sim \text{median}[F(x[k])]$ . The resulting quantile estimates are approximately median-unbiased regardless of the distribution of *x*. (R type 8)
- (3/8,3/8):  $p(k) = (k - 3/8) / (n + 1/4)$ , Blom. The resulting quantile estimates are approximately unbiased if *x* is normally distributed (R type 9)
- (.4,.4): approximately quantile unbiased (Cunnane)
- (.35,.35): APL, used with PWM
- (.3175, .3175): used in `scipy.stats.probplot`

#### Parameters

**data** [array\_like] Input data, as a sequence or array of dimension at most 2.  
**alpha** [float, optional] Plotting positions parameter. Default is 0.4.  
**beta** [float, optional] Plotting positions parameter. Default is 0.4.

#### Returns

**positions** [MaskedArray] The calculated plotting positions.

### scipy.stats.mstats.meppf

`scipy.stats.mstats.meppf` (*data*, *alpha*=0.4, *beta*=0.4)

Returns plotting positions (or empirical percentile points) for the data.

*Plotting positions are defined as  $(i - \alpha) / (n + 1 - \alpha - \beta)$ , where:*

- *i* is the rank order statistics
- *n* is the number of unmasked values along the given axis
- *alpha* and *beta* are two parameters.

*Typical values for alpha and beta are:*

- (0,1):  $p(k) = k/n$ , linear interpolation of cdf (R, type 4)
- (.5,.5):  $p(k) = (k - 1/2) / n$ , piecewise linear function (R, type 5)
- (0,0):  $p(k) = k / (n + 1)$ , Weibull (R type 6)
- (1,1):  $p(k) = (k - 1) / (n - 1)$ , in this case,  $p(k) = \text{mode}[F(x[k])]$ . That's R default (R type 7)
- (1/3,1/3):  $p(k) = (k - 1/3) / (n + 1/3)$ , then  $p(k) \sim \text{median}[F(x[k])]$ . The resulting quantile estimates are approximately median-unbiased regardless of the distribution of *x*. (R type 8)
- (3/8,3/8):  $p(k) = (k - 3/8) / (n + 1/4)$ , Blom. The resulting quantile estimates are approximately unbiased if *x* is normally distributed (R type 9)
- (.4,.4): approximately quantile unbiased (Cunnane)
- (.35,.35): APL, used with PWM
- (.3175, .3175): used in `scipy.stats.probplot`

#### Parameters

**data** [array\_like] Input data, as a sequence or array of dimension at most 2.  
**alpha** [float, optional] Plotting positions parameter. Default is 0.4.  
**beta** [float, optional] Plotting positions parameter. Default is 0.4.

#### Returns

**positions** [MaskedArray] The calculated plotting positions.

### scipy.stats.mstats.moment

`scipy.stats.mstats.moment` (*a*, *moment*=1, *axis*=0)

Calculates the *n*th moment about the mean for a sample.

#### Parameters

**a** [array\_like] data  
**moment** [int, optional] order of central moment that is returned  
**axis** [int or None, optional] Axis along which the central moment is computed. Default is 0. If None, compute over the whole array *a*.

**Returns****n-th central moment**

[ndarray or float] The appropriate moment along the given axis or over all values if axis is None. The denominator for the moment calculation is the number of observations, no degrees of freedom correction is done.

**Notes**

For more details about *moment*, see *stats.moment*.

**scipy.stats.mstats.skew**

`scipy.stats.mstats.skew(a, axis=0, bias=True)`

Computes the skewness of a data set.

**Parameters**

**a** [ndarray] data  
**axis** [int or None, optional] Axis along which skewness is calculated. Default is 0. If None, compute over the whole array *a*.  
**bias** [bool, optional] If False, then the calculations are corrected for statistical bias.

**Returns**

**skewness** [ndarray] The skewness of values along an axis, returning 0 where all values are equal.

**Notes**

For more details about *skew*, see *stats.skew*.

**scipy.stats.mstats.tmean**

`scipy.stats.mstats.tmean(a, limits=None, inclusive=(True, True), axis=None)`

Compute the trimmed mean.

**Parameters**

**a** [array\_like] Array of values.  
**limits** [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None (default), then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval.  
**inclusive** [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).  
**axis** [int or None, optional] Axis along which to operate. If None, compute over the whole array. Default is None.

**Returns**

**tmean** [float]

## Notes

For more details on `tmean`, see `stats.tmean`.

## Examples

```
>>> from scipy.stats import mstats
>>> a = np.array([[6, 8, 3, 0],
... [3, 9, 1, 2],
... [8, 7, 8, 2],
... [5, 6, 0, 2],
... [4, 5, 5, 2]])
...
...
>>> mstats.tmean(a, (2,5))
3.3
>>> mstats.tmean(a, (2,5), axis=0)
masked_array(data=[4.0, 5.0, 4.0, 2.0],
 mask=[False, False, False, False],
 fill_value=1e+20)
```

## scipy.stats.mstats.tvar

`scipy.stats.mstats.tvar` (*a*, *limits=None*, *inclusive=(True, True)*, *axis=0*, *ddof=1*)

Compute the trimmed variance

This function computes the sample variance of an array of values, while ignoring values which are outside of given *limits*.

### Parameters

- a** [array\_like] Array of values.
- limits** [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When *limits* is *None*, then all values are used. Either of the limit values in the tuple can also be *None* representing a half-open interval. The default value is *None*.
- inclusive** [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- axis** [int or None, optional] Axis along which to operate. If *None*, compute over the whole array. Default is zero.
- ddof** [int, optional] Delta degrees of freedom. Default is 1.

### Returns

- tvar** [float] Trimmed variance.

## Notes

For more details on `tvar`, see `stats.tvar`.

**scipy.stats.mstats.tmin**`scipy.stats.mstats.tmin(a, lowerlimit=None, axis=0, inclusive=True)`

Compute the trimmed minimum

**Parameters**

- a** [array\_like] array of values
- lowerlimit** [None or float, optional] Values in the input array less than the given limit will be ignored. When lowerlimit is None, then all values are used. The default value is None.
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- inclusive** [{True, False}, optional] This flag determines whether values exactly equal to the lower limit are included. The default value is True.

**Returns**

- tmin** [float, int or ndarray]

**Notes**For more details on `tmin`, see `stats.tmin`.**Examples**

```

>>> from scipy.stats import mstats
>>> a = np.array([[6, 8, 3, 0],
... [3, 2, 1, 2],
... [8, 1, 8, 2],
... [5, 3, 0, 2],
... [4, 7, 5, 2]])
...
>>> mstats.tmin(a, 5)
masked_array(data=[5, 7, 5, --],
 mask=[False, False, False, True],
 fill_value=999999)

```

**scipy.stats.mstats.tmax**`scipy.stats.mstats.tmax(a, upperlimit=None, axis=0, inclusive=True)`

Compute the trimmed maximum

This function computes the maximum value of an array along a given axis, while ignoring values larger than a specified upper limit.

**Parameters**

- a** [array\_like] array of values
- upperlimit** [None or float, optional] Values in the input array greater than the given limit will be ignored. When upperlimit is None, then all values are used. The default value is None.
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.

**inclusive** [{True, False}, optional] This flag determines whether values exactly equal to the upper limit are included. The default value is True.

**Returns**

**tmax** [float, int or ndarray]

**Notes**

For more details on `tmax`, see `stats.tmax`.

**Examples**

```
>>> from scipy.stats import mstats
>>> a = np.array([[6, 8, 3, 0],
... [3, 9, 1, 2],
... [8, 7, 8, 2],
... [5, 6, 0, 2],
... [4, 5, 5, 2]])
...
...
>>> mstats.tmax(a, 4)
masked_array(data=[4, --, 3, 2],
 mask=[False, True, False, False],
 fill_value=999999)
```

**scipy.stats.mstats.tsem**

`scipy.stats.mstats.tsem(a, limits=None, inclusive=(True, True), axis=0, ddof=1)`

Compute the trimmed standard error of the mean.

This function finds the standard error of the mean for given values, ignoring values outside the given *limits*.

**Parameters**

**a** [array\_like] array of values

**limits** [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When *limits* is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.

**inclusive** [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).

**axis** [int or None, optional] Axis along which to operate. If None, compute over the whole array. Default is zero.

**ddof** [int, optional] Delta degrees of freedom. Default is 1.

**Returns**

**tsem** [float]

## Notes

For more details on `tsem`, see `stats.tsem`.

## scipy.stats.mstats.variation

`scipy.stats.mstats.variation(a, axis=0)`

Computes the coefficient of variation, the ratio of the biased standard deviation to the mean.

### Parameters

**a** [array\_like] Input array.  
**axis** [int or None, optional] Axis along which to calculate the coefficient of variation. Default is 0. If None, compute over the whole array *a*.

### Returns

**variation** [ndarray] The calculated variation along the requested axis.

## Notes

For more details about `variation`, see `stats.variation`.

## scipy.stats.mstats.find\_repeats

`scipy.stats.mstats.find_repeats(arr)`

Find repeats in `arr` and return a tuple (`repeats`, `repeat_count`).

The input is cast to float64. Masked values are discarded.

### Parameters

**arr** [sequence] Input array. The array is flattened if it is not 1D.

### Returns

**repeats** [ndarray] Array of repeated values.  
**counts** [ndarray] Array of counts.

## scipy.stats.mstats.sem

`scipy.stats.mstats.sem(a, axis=0, ddof=1)`

Calculates the standard error of the mean of the input array.

Also sometimes called standard error of measurement.

### Parameters

**a** [array\_like] An array containing the values for which the standard error is returned.  
**axis** [int or None, optional] If axis is None, ravel *a* first. If axis is an integer, this will be the axis over which to operate. Defaults to 0.  
**ddof** [int, optional] Delta degrees-of-freedom. How many degrees of freedom to adjust for bias in limited samples relative to the population estimate of variance. Defaults to 1.

### Returns

**s** [ndarray or float] The standard error of the mean in the sample(s), along the input axis.

## Notes

The default value for *ddof* changed in *scipy* 0.15.0 to be consistent with *stats.sem* as well as with the most common definition used (like in the R documentation).

## Examples

Find standard error along the first axis:

```
>>> from scipy import stats
>>> a = np.arange(20).reshape(5,4)
>>> print(stats.mstats.sem(a))
[2.8284271247461903 2.8284271247461903 2.8284271247461903
 2.8284271247461903]
```

Find standard error across the whole array, using *n* degrees of freedom:

```
>>> print(stats.mstats.sem(a, axis=None, ddof=0))
1.2893796958227628
```

### scipy.stats.mstats.trimmed\_mean

`scipy.stats.mstats.trimmed_mean(a, limits=(0.1, 0.1), inclusive=(1, 1), relative=True, axis=None)`

### scipy.stats.mstats.trimmed\_mean\_ci

`scipy.stats.mstats.trimmed_mean_ci(data, limits=(0.2, 0.2), inclusive=(True, True), alpha=0.05, axis=None)`

Selected confidence interval of the trimmed mean along the given axis.

#### Parameters

<b>data</b>	[array_like] Input data.
<b>limits</b>	[(None, tuple), optional] None or a two item tuple. Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. If <i>n</i> is the number of unmasked data before trimming, then $(n * \text{limits}[0])$ th smallest data and $(n * \text{limits}[1])$ th largest data are masked. The total number of unmasked data after trimming is $n * (1. - \text{sum}(\text{limits}))$ . The value of one limit can be set to None to indicate an open interval. Defaults to (0.2, 0.2).
<b>inclusive</b>	[(2,) tuple of boolean, optional] If <code>relative==False</code> , tuple indicating whether values exactly equal to the absolute limits are allowed. If <code>relative==True</code> , tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False). Defaults to (True, True).
<b>alpha</b>	[float, optional] Confidence level of the intervals. Defaults to 0.05.
<b>axis</b>	[int, optional] Axis along which to cut. If None, uses a flattened version of <i>data</i> . Defaults to None.

#### Returns

**trimmed\_mean\_ci**  
[(2,) ndarray] The lower and upper confidence intervals of the trimmed data.

### scipy.stats.mstats.trimmed\_std

`scipy.stats.mstats.trimmed_std(a, limits=(0.1, 0.1), inclusive=(1, 1), relative=True, axis=None, ddof=0)`

### scipy.stats.mstats.trimmed\_var

`scipy.stats.mstats.trimmed_var(a, limits=(0.1, 0.1), inclusive=(1, 1), relative=True, axis=None, ddof=0)`

## Frequency statistics

---

<code>scoreatpercentile(data, per[, limit, ...])</code>	Calculate the score at the given 'per' percentile of the sequence a.
---------------------------------------------------------	----------------------------------------------------------------------

---

### scipy.stats.mstats.scoreatpercentile

`scipy.stats.mstats.scoreatpercentile(data, per, limit=(), alphap=0.4, betap=0.4)`

Calculate the score at the given 'per' percentile of the sequence a. For example, the score at per=50 is the median.

This function is a shortcut to `mquantile`

## Correlation functions

---

<code>f_oneway(*args)</code>	Performs a 1-way ANOVA, returning an F-value and probability given any number of groups.
<code>pearsonr(x, y)</code>	Calculates a Pearson correlation coefficient and the p-value for testing non-correlation.
<code>spearmanr(x[, y, use_ties, axis, nan_policy])</code>	Calculates a Spearman rank-order correlation coefficient and the p-value to test for non-correlation.
<code>pointbiserialr(x, y)</code>	Calculates a point biserial correlation coefficient and its p-value.
<code>kendalltau(x, y[, use_ties, use_missing, method])</code>	Computes Kendall's rank correlation tau on two variables x and y.
<code>kendalltau_seasonal(x)</code>	Computes a multivariate Kendall's rank correlation tau, for seasonal data.
<code>linregress(x[, y])</code>	Linear regression calculation
<code>siegelslopes(y[, x, method])</code>	Computes the Siegel estimator for a set of points (x, y).
<code>theilslopes(y[, x, alpha])</code>	Computes the Theil-Sen estimator for a set of points (x, y).
<code>sen_seasonal_slopes(x)</code>	

---

### scipy.stats.mstats.f\_oneway

`scipy.stats.mstats.f_oneway(*args)`

Performs a 1-way ANOVA, returning an F-value and probability given any number of groups. From Heiman, pp.394-7.

Usage: `f_oneway(*args)`, where `*args` is 2 or more arrays, one per treatment group.

#### Returns

**statistic** [float] The computed F-value of the test.

**pvalue** [float] The associated p-value from the F-distribution.

### scipy.stats.mstats.pearsonr

`scipy.stats.mstats.pearsonr(x, y)`

Calculates a Pearson correlation coefficient and the p-value for testing non-correlation.

The Pearson correlation coefficient measures the linear relationship between two datasets. Strictly speaking, Pearson's correlation requires that each dataset be normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact linear relationship. Positive correlations imply that as  $x$  increases, so does  $y$ . Negative correlations imply that as  $x$  increases,  $y$  decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Pearson correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

#### Parameters

**x** [1-D array\_like] Input  
**y** [1-D array\_like] Input

#### Returns

**pearsonr** [float] Pearson's correlation coefficient, 2-tailed p-value.

### References

<http://www.statsoft.com/textbook/glosp.html#Pearson%20Correlation>

### scipy.stats.mstats.spearmanr

`scipy.stats.mstats.spearmanr(x, y=None, use_ties=True, axis=None, nan_policy='propagate')`

Calculates a Spearman rank-order correlation coefficient and the p-value to test for non-correlation.

The Spearman correlation is a nonparametric measure of the linear relationship between two datasets. Unlike the Pearson correlation, the Spearman correlation does not assume that both datasets are normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply a monotonic relationship. Positive correlations imply that as  $x$  increases, so does  $y$ . Negative correlations imply that as  $x$  increases,  $y$  decreases.

Missing values are discarded pair-wise: if a value is missing in  $x$ , the corresponding value in  $y$  is masked.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Spearman correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

#### Parameters

**x, y** [1D or 2D array\_like, y is optional] One or two 1-D or 2-D arrays containing multiple variables and observations. When these are 1-D, each represents a vector of observations of a single variable. For the behavior in the 2-D case, see under `axis`, below.  
**use\_ties** [bool, optional] DO NOT USE. Does not do anything, keyword is only left in place for backwards compatibility reasons.

**axis** [int or None, optional] If axis=0 (default), then each column represents a variable, with observations in the rows. If axis=1, the relationship is transposed: each row represents a variable, while the columns contain observations. If axis=None, then both arrays will be raveled.

**nan\_policy** [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

**Returns**

**correlation** [float] Spearman correlation coefficient

**pvalue** [float] 2-tailed p-value.

**References**

[CRCProbStat2000] section 14.7

**scipy.stats.mstats.pointbiserialr**

`scipy.stats.mstats.pointbiserialr(x, y)`  
 Calculates a point biserial correlation coefficient and its p-value.

**Parameters**

**x** [array\_like of bools] Input array.

**y** [array\_like] Input array.

**Returns**

**correlation** [float] R value

**pvalue** [float] 2-tailed p-value

**Notes**

Missing values are considered pair-wise: if a value is missing in x, the corresponding value in y is masked.  
 For more details on `pointbiserialr`, see `stats.pointbiserialr`.

**scipy.stats.mstats.kendalltau**

`scipy.stats.mstats.kendalltau(x, y, use_ties=True, use_missing=False, method='auto')`  
 Computes Kendall’s rank correlation tau on two variables x and y.

**Parameters**

**x** [sequence] First data list (for example, time).

**y** [sequence] Second data list.

**use\_ties** [{True, False}, optional] Whether ties correction should be performed.

**use\_missing** [{False, True}, optional] Whether missing data should be allocated a rank of 0 (False) or the average rank (True)

**method:** {'auto', 'asymptotic', 'exact'}, optional

Defines which method is used to calculate the p-value [1]. 'asymptotic' uses a normal approximation valid for large samples. 'exact' computes the exact p-value, but can only be used if no ties are present. 'auto' is the default and selects the appropriate method based on a trade-off between speed and accuracy.

#### Returns

**correlation**

[float] Kendall tau

**pvalue**

[float] Approximate 2-side p-value.

## References

[1]

### scipy.stats.mstats.kendalltau\_seasonal

`scipy.stats.mstats.kendalltau_seasonal(x)`

Computes a multivariate Kendall's rank correlation tau, for seasonal data.

#### Parameters

**x** [2-D ndarray] Array of seasonal data, with seasons in columns.

### scipy.stats.mstats.linregress

`scipy.stats.mstats.linregress(x, y=None)`

Linear regression calculation

Note that the non-masked version is used, and that this docstring is replaced by the non-masked docstring + some info on missing data.

### scipy.stats.mstats.siegel slopes

`scipy.stats.mstats.siegel slopes(y, x=None, method='hierarchical')`

Computes the Siegel estimator for a set of points (x, y).

`siegel slopes` implements a method for robust linear regression using repeated medians to fit a line to the points (x, y). The method is robust to outliers with an asymptotic breakdown point of 50%.

#### Parameters

**y** [array\_like] Dependent variable.

**x** [array\_like or None, optional] Independent variable. If None, use `arange(len(y))` instead.

**method** [{'hierarchical', 'separate'}] If 'hierarchical', estimate the intercept using the estimated slope `medslope` (default option). If 'separate', estimate the intercept independent of the estimated slope. See Notes for details.

#### Returns

**medslope** [float] Estimate of the slope of the regression line.

**medintercept**

[float] Estimate of the intercept of the regression line.

See also:

[theilslopes](#)

a similar technique without repeated medians

Notes

For more details on [siegeleslopes](#), see `scipy.stats.siegeleslopes`.

### `scipy.stats.mstats.theilslopes`

`scipy.stats.mstats.theilslopes` (*y*, *x=None*, *alpha=0.95*)

Computes the Theil-Sen estimator for a set of points (*x*, *y*).

[theilslopes](#) implements a method for robust linear regression. It computes the slope as the median of all slopes between paired values.

#### Parameters

- y** [array\_like] Dependent variable.
- x** [array\_like or None, optional] Independent variable. If None, use `arange(len(y))` instead.
- alpha** [float, optional] Confidence degree between 0 and 1. Default is 95% confidence. Note that *alpha* is symmetric around 0.5, i.e. both 0.1 and 0.9 are interpreted as “find the 90% confidence interval”.

#### Returns

- medslope** [float] Theil slope.
- medintercept** [float] Intercept of the Theil line, as `median(y) - medslope*median(x)`.
- lo\_slope** [float] Lower bound of the confidence interval on *medslope*.
- up\_slope** [float] Upper bound of the confidence interval on *medslope*.

See also:

[siegeleslopes](#)

a similar technique with repeated medians

Notes

For more details on [theilslopes](#), see `stats.theilslopes`.

### `scipy.stats.mstats.sen_seasonal_slopes`

`scipy.stats.mstats.sen_seasonal_slopes` (*x*)

Table 270 – continued from previous page

**Statistical tests**

<code>ttest_1samp(a, popmean[, axis])</code>	Calculates the T-test for the mean of ONE group of scores.
<code>ttest_onesamp(a, popmean[, axis])</code>	Calculates the T-test for the mean of ONE group of scores.
<code>ttest_ind(a, b[, axis, equal_var])</code>	Calculates the T-test for the means of TWO INDEPENDENT samples of scores.
<code>ttest_rel(a, b[, axis])</code>	Calculates the T-test on TWO RELATED samples of scores, a and b.
<code>chisquare(f_obs[, f_exp, ddof, axis])</code>	Calculate a one-way chi square test.
<code>ks_2samp(data1, data2[, alternative])</code>	Computes the Kolmogorov-Smirnov test on two samples.
<code>ks_twosamp(data1, data2[, alternative])</code>	Computes the Kolmogorov-Smirnov test on two samples.
<code>mannwhitneyu(x, y[, use_continuity])</code>	Computes the Mann-Whitney statistic
<code>rankdata(data[, axis, use_missing])</code>	Returns the rank (also known as order statistics) of each data point along the given axis.
<code>kruskal(*args)</code>	Compute the Kruskal-Wallis H-test for independent samples
<code>kruskalwallis(*args)</code>	Compute the Kruskal-Wallis H-test for independent samples
<code>friedmanchisquare(*args)</code>	Friedman Chi-Square is a non-parametric, one-way within-subjects ANOVA.
<code>brunnermunzel(x, y[, alternative, distribution])</code>	Computes the Brunner-Munzel test on samples x and y
<code>skewtest(a[, axis])</code>	Tests whether the skew is different from the normal distribution.
<code>kurtosistest(a[, axis])</code>	Tests whether a dataset has normal kurtosis
<code>normaltest(a[, axis])</code>	Tests whether a sample differs from a normal distribution.

**scipy.stats.mstats.ttest\_1samp**

`scipy.stats.mstats.ttest_1samp(a, popmean, axis=0)`

Calculates the T-test for the mean of ONE group of scores.

**Parameters**

<b>a</b>	[array_like] sample observation
<b>popmean</b>	[float or array_like] expected value in null hypothesis, if array_like than it must have the same shape as <i>a</i> excluding the axis dimension
<b>axis</b>	[int or None, optional] Axis along which to compute test. If None, compute over the whole array <i>a</i> .

**Returns**

<b>statistic</b>	[float or array] t-statistic
<b>pvalue</b>	[float or array] two-tailed p-value

**Notes**

For more details on `ttest_1samp`, see `stats.ttest_1samp`.

### scipy.stats.mstats.ttest\_onesamp

`scipy.stats.mstats.ttest_onesamp(a, popmean, axis=0)`

Calculates the T-test for the mean of ONE group of scores.

#### Parameters

- a** [array\_like] sample observation
- popmean** [float or array\_like] expected value in null hypothesis, if array\_like than it must have the same shape as *a* excluding the axis dimension
- axis** [int or None, optional] Axis along which to compute test. If None, compute over the whole array *a*.

#### Returns

- statistic** [float or array] t-statistic
- pvalue** [float or array] two-tailed p-value

#### Notes

For more details on `ttest_1samp`, see `stats.ttest_1samp`.

### scipy.stats.mstats.ttest\_ind

`scipy.stats.mstats.ttest_ind(a, b, axis=0, equal_var=True)`

Calculates the T-test for the means of TWO INDEPENDENT samples of scores.

#### Parameters

- a, b** [array\_like] The arrays must have the same shape, except in the dimension corresponding to *axis* (the first, by default).
- axis** [int or None, optional] Axis along which to compute test. If None, compute over the whole arrays, *a*, and *b*.
- equal\_var** [bool, optional] If True, perform a standard independent 2 sample test that assumes equal population variances. If False, perform Welch's t-test, which does not assume equal population variance.  
New in version 0.17.0.

#### Returns

- statistic** [float or array] The calculated t-statistic.
- pvalue** [float or array] The two-tailed p-value.

#### Notes

For more details on `ttest_ind`, see `stats.ttest_ind`.

### scipy.stats.mstats.ttest\_rel

`scipy.stats.mstats.ttest_rel(a, b, axis=0)`

Calculates the T-test on TWO RELATED samples of scores, a and b.

#### Parameters

- a, b** [array\_like] The arrays must have the same shape.

**axis** [int or None, optional] Axis along which to compute test. If None, compute over the whole arrays, *a*, and *b*.

**Returns**

**statistic** [float or array] t-statistic  
**pvalue** [float or array] two-tailed p-value

**Notes**

For more details on `ttest_rel`, see `stats.ttest_rel`.

**scipy.stats.mstats.chisquare**

`scipy.stats.mstats.chisquare` (*f\_obs*, *f\_exp=None*, *ddof=0*, *axis=0*)

Calculate a one-way chi square test.

The chi square test tests the null hypothesis that the categorical data has the given frequencies.

**Parameters**

**f\_obs** [array\_like] Observed frequencies in each category.  
**f\_exp** [array\_like, optional] Expected frequencies in each category. By default the categories are assumed to be equally likely.  
**ddof** [int, optional] “Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with  $k - 1 - \text{ddof}$  degrees of freedom, where *k* is the number of observed frequencies. The default value of *ddof* is 0.  
**axis** [int or None, optional] The axis of the broadcast result of *f\_obs* and *f\_exp* along which to apply the test. If axis is None, all values in *f\_obs* are treated as a single data set. Default is 0.

**Returns**

**chisq** [float or ndarray] The chi-squared test statistic. The value is a float if *axis* is None or *f\_obs* and *f\_exp* are 1-D.  
**p** [float or ndarray] The p-value of the test. The value is a float if *ddof* and the return value *chisq* are scalars.

**See also:**

`scipy.stats.power_divergence`

**Notes**

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5.

The default degrees of freedom, *k*-1, are for the case when no parameters of the distribution are estimated. If *p* parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are *k*-1-*p*. If the parameters are estimated in a different way, then the dof can be between *k*-1-*p* and *k*-1. However, it is also possible that the asymptotic distribution is not a chisquare, in which case this test is not appropriate.

**References**

[1], [2]

## Examples

When just *f\_obs* is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies.

```
>>> from scipy.stats import chisquare
>>> chisquare([16, 18, 16, 14, 12, 12])
(2.0, 0.84914503608460956)
```

With *f\_exp* the expected frequencies can be given.

```
>>> chisquare([16, 18, 16, 14, 12, 12], f_exp=[16, 16, 16, 16, 16, 8])
(3.5, 0.62338762774958223)
```

When *f\_obs* is 2-D, by default the test is applied to each column.

```
>>> obs = np.array([[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]])
>>> obs.shape
(6, 2)
>>> chisquare(obs)
(array([2. , 6.66666667]), array([0.84914504, 0.24663415]))
```

By setting *axis=None*, the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```
>>> chisquare(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> chisquare(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

*ddof* is the change to make to the default degrees of freedom.

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.73575888234288467)
```

The calculation of the p-values is done by broadcasting the chi-squared statistic with *ddof*.

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([0.84914504, 0.73575888, 0.5724067]))
```

*f\_obs* and *f\_exp* are also broadcast. In the following, *f\_obs* has shape (6,) and *f\_exp* has shape (2, 6), so the result of broadcasting *f\_obs* and *f\_exp* has shape (2, 6). To compute the desired chi-squared statistics, we use *axis=1*:

```
>>> chisquare([16, 18, 16, 14, 12, 12],
... f_exp=[[16, 16, 16, 16, 16, 8], [8, 20, 20, 16, 12, 12]],
... axis=1)
(array([3.5 , 9.25]), array([0.62338763, 0.09949846]))
```

## scipy.stats.mstats.ks\_2samp

`scipy.stats.mstats.ks_2samp` (*data1*, *data2*, *alternative='two-sided'*)

Computes the Kolmogorov-Smirnov test on two samples.

Missing values are discarded.

**Parameters**

<b>data1</b>	[array_like] First data set
<b>data2</b>	[array_like] Second data set
<b>alternative</b>	[{'two-sided', 'less', 'greater'}, optional] Indicates the alternative hypothesis. Default is 'two-sided'.

**Returns**

<b>d</b>	[float] Value of the Kolmogorov Smirnov test
<b>p</b>	[float] Corresponding p-value.

**scipy.stats.mstats.ks\_twosamp**

`scipy.stats.mstats.ks_twosamp(data1, data2, alternative='two-sided')`

Computes the Kolmogorov-Smirnov test on two samples.

Missing values are discarded.

**Parameters**

<b>data1</b>	[array_like] First data set
<b>data2</b>	[array_like] Second data set
<b>alternative</b>	[{'two-sided', 'less', 'greater'}, optional] Indicates the alternative hypothesis. Default is 'two-sided'.

**Returns**

<b>d</b>	[float] Value of the Kolmogorov Smirnov test
<b>p</b>	[float] Corresponding p-value.

**scipy.stats.mstats.mannwhitneyu**

`scipy.stats.mstats.mannwhitneyu(x, y, use_continuity=True)`

Computes the Mann-Whitney statistic

Missing values in  $x$  and/or  $y$  are discarded.

**Parameters**

<b>x</b>	[sequence] Input
<b>y</b>	[sequence] Input
<b>use_continuity</b>	[{True, False}, optional] Whether a continuity correction (1/2.) should be taken into account.

**Returns**

<b>statistic</b>	[float] The Mann-Whitney statistics
<b>pvalue</b>	[float] Approximate p-value assuming a normal distribution.

## scipy.stats.mstats.rankdata

`scipy.stats.mstats.rankdata` (*data*, *axis=None*, *use\_missing=False*)

Returns the rank (also known as order statistics) of each data point along the given axis.

If some values are tied, their rank is averaged. If some values are masked, their rank is set to 0 if `use_missing` is False, or set to the average rank of the unmasked values if `use_missing` is True.

### Parameters

<b>data</b>	[sequence] Input data. The data is transformed to a masked array
<b>axis</b>	[{None,int}, optional] Axis along which to perform the ranking. If None, the array is first flattened. An exception is raised if the axis is specified for arrays with a dimension larger than 2
<b>use_missing</b>	[bool, optional] Whether the masked values have a rank of 0 (False) or equal to the average rank of the unmasked values (True).

## scipy.stats.mstats.kruskal

`scipy.stats.mstats.kruskal` (\*args)

Compute the Kruskal-Wallis H-test for independent samples

### Parameters

<b>sample1, sample2, ...</b>	[array_like] Two or more arrays with the sample measurements can be given as arguments.
------------------------------	-----------------------------------------------------------------------------------------

### Returns

<b>statistic</b>	[float] The Kruskal-Wallis H statistic, corrected for ties
<b>pvalue</b>	[float] The p-value for the test using the assumption that H has a chi square distribution

## Notes

For more details on `kruskal`, see `stats.kruskal`.

## Examples

```
>>> from scipy.stats.mstats import kruskal
```

Random samples from three different brands of batteries were tested to see how long the charge lasted. Results were as follows:

```
>>> a = [6.3, 5.4, 5.7, 5.2, 5.0]
>>> b = [6.9, 7.0, 6.1, 7.9]
>>> c = [7.2, 6.9, 6.1, 6.5]
```

Test the hypothesis that the distribution functions for all of the brands' durations are identical. Use 5% level of significance.

```
>>> kruskal(a, b, c)
KruskalResult(statistic=7.113812154696133, pvalue=0.028526948491942164)
```

The null hypothesis is rejected at the 5% level of significance because the returned p-value is less than the critical value of 5%.

### scipy.stats.mstats.kruskalwallis

`scipy.stats.mstats.kruskalwallis(*args)`

Compute the Kruskal-Wallis H-test for independent samples

#### Parameters

**sample1, sample2, ...**

[array\_like] Two or more arrays with the sample measurements can be given as arguments.

#### Returns

**statistic** [float] The Kruskal-Wallis H statistic, corrected for ties

**pvalue** [float] The p-value for the test using the assumption that H has a chi square distribution

### Notes

For more details on *kruskal*, see *stats.kruskal*.

### Examples

```
>>> from scipy.stats.mstats import kruskal
```

Random samples from three different brands of batteries were tested to see how long the charge lasted. Results were as follows:

```
>>> a = [6.3, 5.4, 5.7, 5.2, 5.0]
>>> b = [6.9, 7.0, 6.1, 7.9]
>>> c = [7.2, 6.9, 6.1, 6.5]
```

Test the hypothesis that the distribution functions for all of the brands' durations are identical. Use 5% level of significance.

```
>>> kruskal(a, b, c)
KruskalResult(statistic=7.113812154696133, pvalue=0.028526948491942164)
```

The null hypothesis is rejected at the 5% level of significance because the returned p-value is less than the critical value of 5%.

### scipy.stats.mstats.friedmanchisquare

`scipy.stats.mstats.friedmanchisquare(*args)`

Friedman Chi-Square is a non-parametric, one-way within-subjects ANOVA. This function calculates the Friedman Chi-square test for repeated measures and returns the result, along with the associated probability value.

Each input is considered a given group. Ideally, the number of treatments among each group should be equal. If this is not the case, only the first n treatments are taken into account, where n is the number of treatments of the smallest group. If a group has some missing values, the corresponding treatments are masked in the other groups. The test statistic is corrected for ties.

Masked values in one group are propagated to the other groups.

**Returns**

**statistic** [float] the test statistic.  
**pvalue** [float] the associated p-value.

**scipy.stats.mstats.brunnermunzel**

`scipy.stats.mstats.brunnermunzel` (*x*, *y*, *alternative*='two-sided', *distribution*='t')

Computes the Brunner-Munzel test on samples *x* and *y*

Missing values in *x* and/or *y* are discarded.

**Parameters**

**x, y** [array\_like] Array of samples, should be one-dimensional.  
**alternative** ['less', 'two-sided', or 'greater', optional] Whether to get the p-value for the one-sided hypothesis ('less' or 'greater') or for the two-sided hypothesis ('two-sided'). Defaults value is 'two-sided'.  
**distribution: 't' or 'normal', optional**  
 Whether to get the p-value by t-distribution or by standard normal distribution. Defaults value is 't'.

**Returns**

**statistic** [float] The Brunner-Munzer W statistic.  
**pvalue** [float] p-value assuming an t distribution. One-sided or two-sided, depending on the choice of *alternative* and *distribution*.

See also:

**mannwhitneyu**

Mann-Whitney rank test on two samples.

**Notes**

For more details on *brunnermunzel*, see *stats.brunnermunzel*.

**scipy.stats.mstats.skewtest**

`scipy.stats.mstats.skewtest` (*a*, *axis*=0)

Tests whether the skew is different from the normal distribution.

**Parameters**

**a** [array] The data to be tested  
**axis** [int or None, optional] Axis along which statistics are calculated. Default is 0. If None, compute over the whole array *a*.

**Returns**

**statistic** [float] The computed z-score for this test.  
**pvalue** [float] a 2-sided p-value for the hypothesis test

## Notes

For more details about `skewtest`, see `stats.skewtest`.

### scipy.stats.mstats.kurtosistest

`scipy.stats.mstats.kurtosistest` (*a*, *axis=0*)

Tests whether a dataset has normal kurtosis

#### Parameters

**a** [array] array of the sample data

**axis** [int or None, optional] Axis along which to compute test. Default is 0. If None, compute over the whole array *a*.

#### Returns

**statistic** [float] The computed z-score for this test.

**pvalue** [float] The 2-sided p-value for the hypothesis test

## Notes

For more details about `kurtosistest`, see `stats.kurtosistest`.

### scipy.stats.mstats.normaltest

`scipy.stats.mstats.normaltest` (*a*, *axis=0*)

Tests whether a sample differs from a normal distribution.

#### Parameters

**a** [array\_like] The array containing the data to be tested.

**axis** [int or None, optional] Axis along which to compute test. Default is 0. If None, compute over the whole array *a*.

#### Returns

**statistic** [float or array]  $s^2 + k^2$ , where *s* is the z-score returned by `skewtest` and *k* is the z-score returned by `kurtosistest`.

**pvalue** [float or array] A 2-sided chi squared probability for the hypothesis test.

## Notes

For more details about `normaltest`, see `stats.normaltest`.

## Transformations

<code>obrientransform(*args)</code>	Computes a transform on input data (any number of columns).
<code>trim(a[, limits, inclusive, relative, axis])</code>	Trims an array by masking the data outside some given limits.
<code>trima(a[, limits, inclusive])</code>	Trims an array by masking the data outside some given limits.

Continued on next page

Table 271 – continued from previous page

<code>trimmed_stde(a[, limits, inclusive, axis])</code>	Returns the standard error of the trimmed mean along the given axis.
<code>trimr(a[, limits, inclusive, axis])</code>	Trims an array by masking some proportion of the data on each end.
<code>trimtail(data[, proportiontocut, tail, ...])</code>	Trims the data by masking values from one tail.
<code>trimboth(data[, proportiontocut, inclusive, ...])</code>	Trims the smallest and largest data values.
<code>winsorize(a[, limits, inclusive, inplace, axis])</code>	Returns a Winsorized version of the input array.
<code>zmap(scores, compare[, axis, ddof])</code>	Calculate the relative z-scores.
<code>zscore(a[, axis, ddof])</code>	Calculate the z score of each value in the sample, relative to the sample mean and standard deviation.

**scipy.stats.mstats.obrientransform**

`scipy.stats.mstats.obrientransform(*args)`

Computes a transform on input data (any number of columns). Used to test for homogeneity of variance prior to running one-way stats. Each array in `*args` is one level of a factor. If an `f_oneway()` run on the transformed data and found significant, variances are unequal. From Maxwell and Delaney, p.112.

Returns: transformed data for use in an ANOVA

**scipy.stats.mstats.trim**

`scipy.stats.mstats.trim(a, limits=None, inclusive=(True, True), relative=False, axis=None)`

Trims an array by masking the data outside some given limits.

Returns a masked version of the input array.

**Parameters**

<b>a</b>	[sequence] Input array
<b>limits</b>	[[None, tuple], optional] If <i>relative</i> is False, tuple (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit are masked. If <i>relative</i> is True, tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data. Noting <i>n</i> the number of unmasked data before trimming, the ( $n \cdot \text{limits}[0]$ )th smallest data and the ( $n \cdot \text{limits}[1]$ )th largest data are masked, and the total number of unmasked data after trimming is $n \cdot (1 - \text{sum}(\text{limits}))$ . In each case, the value of one limit can be set to None to indicate an open interval. If <i>limits</i> is None, no trimming is performed
<b>inclusive</b>	[(bool, bool) tuple], optional] If <i>relative</i> is False, tuple indicating whether values exactly equal to the absolute limits are allowed. If <i>relative</i> is True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
<b>relative</b>	[bool, optional] Whether to consider the limits as absolute values (False) or proportions to cut (True).
<b>axis</b>	[int, optional] Axis along which to trim.

**Examples**

```
>>> from scipy.stats.mstats import trim
>>> z = [1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
>>> print(trim(z, (3, 8)))
```

(continues on next page)

(continued from previous page)

```
[-- -- 3 4 5 6 7 8 -- --]
>>> print(trim(z, (0.1, 0.2), relative=True))
[-- 2 3 4 5 6 7 8 -- --]
```

### scipy.stats.mstats.trima

`scipy.stats.mstats.trima` (*a*, *limits=None*, *inclusive=(True, True)*)

Trims an array by masking the data outside some given limits.

Returns a masked version of the input array.

#### Parameters

- a** [array\_like] Input array.
- limits** [{None, tuple}, optional] Tuple of (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit will be masked. A limit is None indicates an open interval.
- inclusive** [(bool, bool) tuple, optional] Tuple of (lower flag, upper flag), indicating whether values exactly equal to the lower (upper) limit are allowed.

### scipy.stats.mstats.trimmed\_stde

`scipy.stats.mstats.trimmed_stde` (*a*, *limits=(0.1, 0.1)*, *inclusive=(1, 1)*, *axis=None*)

Returns the standard error of the trimmed mean along the given axis.

#### Parameters

- a** [sequence] Input array
- limits** [{(0.1, 0.1), tuple of float}, optional] tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data.  
If *n* is the number of unmasked data before trimming, the values smaller than  $n * \text{limits}[0]$  and the values larger than  $n * \text{limits}[1]$  are masked, and the total number of unmasked data after trimming is  $n * (1 - \text{sum}(\text{limits}))$ . In each case, the value of one limit can be set to None to indicate an open interval. If *limits* is None, no trimming is performed.
- inclusive** [{(bool, bool) tuple} optional] Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
- axis** [int, optional] Axis along which to trim.

#### Returns

- trimmed\_stde** [scalar or ndarray]

### scipy.stats.mstats.trimr

`scipy.stats.mstats.trimr` (*a*, *limits=None*, *inclusive=(True, True)*, *axis=None*)

Trims an array by masking some proportion of the data on each end. Returns a masked version of the input array.

#### Parameters

- a** [sequence] Input array.

- limits** [None, tuple], optional] Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. Noting  $n$  the number of unmasked data before trimming, the  $(n*\text{limits}[0])$ th smallest data and the  $(n*\text{limits}[1])$ th largest data are masked, and the total number of unmasked data after trimming is  $n*(1-\text{sum}(\text{limits}))$ . The value of one limit can be set to None to indicate an open interval.
- inclusive** [(True,True) tuple], optional] Tuple of flags indicating whether the number of data being masked on the left (right) end should be truncated (True) or rounded (False) to integers.
- axis** [None,int], optional] Axis along which to trim. If None, the whole array is trimmed, but its shape is maintained.

### scipy.stats.mstats.trimtail

`scipy.stats.mstats.trimtail` (*data*, *proportiontocut*=0.2, *tail*='left', *inclusive*=(True, True), *axis*=None)

Trims the data by masking values from one tail.

#### Parameters

- data** [array\_like] Data to trim.
- proportiontocut** [float, optional] Percentage of trimming. If  $n$  is the number of unmasked values before trimming, the number of values after trimming is  $(1 - \text{proportiontocut}) * n$ . Default is 0.2.
- tail** [{'left','right'}], optional] If 'left' the *proportiontocut* lowest values will be masked. If 'right' the *proportiontocut* highest values will be masked. Default is 'left'.
- inclusive** [(bool, bool) tuple], optional] Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False). Default is (True, True).
- axis** [int, optional] Axis along which to perform the trimming. If None, the input array is first flattened. Default is None.

#### Returns

- trimtail** [ndarray] Returned array of same shape as *data* with masked tail values.

### scipy.stats.mstats.trimboth

`scipy.stats.mstats.trimboth` (*data*, *proportiontocut*=0.2, *inclusive*=(True, True), *axis*=None)

Trims the smallest and largest data values.

Trims the *data* by masking the  $\text{int}(\text{proportiontocut} * n)$  smallest and  $\text{int}(\text{proportiontocut} * n)$  largest values of data along the given axis, where  $n$  is the number of unmasked values before trimming.

#### Parameters

- data** [ndarray] Data to trim.
- proportiontocut** [float, optional] Percentage of trimming (as a float between 0 and 1). If  $n$  is the number of unmasked values before trimming, the number of values after trimming is  $(1 - 2*\text{proportiontocut}) * n$ . Default is 0.2.
- inclusive** [(bool, bool) tuple], optional] Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
- axis** [int, optional] Axis along which to perform the trimming. If None, the input array is first flattened.

**scipy.stats.mstats.winsorize**

`scipy.stats.mstats.winsorize` (*a*, *limits=None*, *inclusive=(True, True)*, *inplace=False*, *axis=None*)

Returns a Winsorized version of the input array.

The (*limits*[0])th lowest values are set to the (*limits*[0])th percentile, and the (*limits*[1])th highest values are set to the (1 - *limits*[1])th percentile. Masked values are skipped.

**Parameters**

<b>a</b>	[sequence] Input array.
<b>limits</b>	[[None, tuple of float], optional] Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. Noting <i>n</i> the number of unmasked data before trimming, the ( <i>n</i> * <i>limits</i> [0])th smallest data and the ( <i>n</i> * <i>limits</i> [1])th largest data are masked, and the total number of unmasked data after trimming is <i>n</i> *(1.-sum( <i>limits</i> )). The value of one limit can be set to None to indicate an open interval.
<b>inclusive</b>	[(True, True) tuple], optional] Tuple indicating whether the number of data being masked on each side should be truncated (True) or rounded (False).
<b>inplace</b>	[[False, True], optional] Whether to winsorize in place (True) or to use a copy (False)
<b>axis</b>	[[None, int], optional] Axis along which to trim. If None, the whole array is trimmed, but its shape is maintained.

**Notes**

This function is applied to reduce the effect of possibly spurious outliers by limiting the extreme values.

**scipy.stats.mstats.zmap**

`scipy.stats.mstats.zmap` (*scores*, *compare*, *axis=0*, *ddof=0*)

Calculate the relative z-scores.

Return an array of z-scores, i.e., scores that are standardized to zero mean and unit variance, where mean and variance are calculated from the comparison array.

**Parameters**

<b>scores</b>	[array_like] The input for which z-scores are calculated.
<b>compare</b>	[array_like] The input from which the mean and standard deviation of the normalization are taken; assumed to have the same dimension as <i>scores</i> .
<b>axis</b>	[int or None, optional] Axis over which mean and variance of <i>compare</i> are calculated. Default is 0. If None, compute over the whole array <i>scores</i> .
<b>ddof</b>	[int, optional] Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

**Returns**

<b>zscore</b>	[array_like] Z-scores, in the same shape as <i>scores</i> .
---------------	-------------------------------------------------------------

**Notes**

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses *asanyarray* instead of *asarray* for parameters).

## Examples

```
>>> from scipy.stats import zmap
>>> a = [0.5, 2.0, 2.5, 3]
>>> b = [0, 1, 2, 3, 4]
>>> zmap(a, b)
array([-1.06066017, 0. , 0.35355339, 0.70710678])
```

## scipy.stats.mstats.zscore

`scipy.stats.mstats.zscore(a, axis=0, ddof=0)`

Calculate the z score of each value in the sample, relative to the sample mean and standard deviation.

### Parameters

- a** [array\_like] An array like object containing the sample data.
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- ddof** [int, optional] Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

### Returns

- zscore** [array\_like] The z-scores, standardized by mean and standard deviation of input array *a*.

## Notes

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses *asanyarray* instead of *asarray* for parameters).

## Examples

```
>>> a = np.array([0.7972, 0.0767, 0.4383, 0.7866, 0.8091,
... 0.1954, 0.6307, 0.6599, 0.1065, 0.0508])
>>> from scipy import stats
>>> stats.zscore(a)
array([1.1273, -1.247 , -0.0552, 1.0923, 1.1664, -0.8559, 0.5786,
 0.6748, -1.1488, -1.3324])
```

Computing along a specified axis, using n-1 degrees of freedom (`ddof=1`) to calculate the standard deviation:

```
>>> b = np.array([[0.3148, 0.0478, 0.6243, 0.4608],
... [0.7149, 0.0775, 0.6072, 0.9656],
... [0.6341, 0.1403, 0.9759, 0.4064],
... [0.5918, 0.6948, 0.904 , 0.3721],
... [0.0921, 0.2481, 0.1188, 0.1366]])
>>> stats.zscore(b, axis=1, ddof=1)
array([[-0.19264823, -1.28415119, 1.07259584, 0.40420358],
 [0.33048416, -1.37380874, 0.04251374, 1.00081084],
 [0.26796377, -1.12598418, 1.23283094, -0.37481053],
 [-0.22095197, 0.24468594, 1.19042819, -1.21416216],
 [-0.82780366, 1.4457416 , -0.43867764, -0.1792603]])
```

**Other**

<code>argstoarray(*args)</code>	Constructs a 2D array from a group of sequences.
<code>count_tied_groups(x[, use_missing])</code>	Counts the number of tied values.
<code>msign(x)</code>	Returns the sign of $x$ , or 0 if $x$ is masked.
<code>compare_medians_ms(group_1, group_2[, axis])</code>	Compares the medians from two independent groups along the given axis.
<code>median_cihs(data[, alpha, axis])</code>	Computes the alpha-level confidence interval for the median of the data.
<code>mjci(data[, prob, axis])</code>	Returns the Maritz-Jarrett estimators of the standard error of selected experimental quantiles of the data.
<code>mquantiles_cimj(data[, prob, alpha, axis])</code>	Computes the alpha confidence interval for the selected quantiles of the data, with Maritz-Jarrett estimators.
<code>rsh(data[, points])</code>	Evaluates Rosenblatt's shifted histogram estimators for each data point.

**scipy.stats.mstats.argstoarray**

`scipy.stats.mstats.argstoarray(*args)`  
Constructs a 2D array from a group of sequences.

Sequences are filled with missing values to match the length of the longest sequence.

**Parameters**

**args** [sequences] Group of sequences.

**Returns**

**argstoarray**  
[MaskedArray] A ( $m \times n$ ) masked array, where  $m$  is the number of arguments and  $n$  the length of the longest argument.

**Notes**

`numpy.ma.row_stack` has identical behavior, but is called with a sequence of sequences.

**scipy.stats.mstats.count\_tied\_groups**

`scipy.stats.mstats.count_tied_groups(x, use_missing=False)`  
Counts the number of tied values.

**Parameters**

**x** [sequence] Sequence of data on which to counts the ties  
**use\_missing** [bool, optional] Whether to consider missing values as tied.

**Returns**

**count\_tied\_groups**  
[dict] Returns a dictionary (nb of ties: nb of groups).

## Examples

```
>>> from scipy.stats import mstats
>>> z = [0, 0, 0, 2, 2, 2, 3, 3, 4, 5, 6]
>>> mstats.count_tied_groups(z)
{2: 1, 3: 2}
```

In the above example, the ties were 0 (3x), 2 (3x) and 3 (2x).

```
>>> z = np.ma.array([0, 0, 1, 2, 2, 2, 3, 3, 4, 5, 6])
>>> mstats.count_tied_groups(z)
{2: 2, 3: 1}
>>> z[[1,-1]] = np.ma.masked
>>> mstats.count_tied_groups(z, use_missing=True)
{2: 2, 3: 1}
```

## scipy.stats.mstats.msign

`scipy.stats.mstats.msign(x)`

Returns the sign of *x*, or 0 if *x* is masked.

## scipy.stats.mstats.compare\_medians\_ms

`scipy.stats.mstats.compare_medians_ms(group_1, group_2, axis=None)`

Compares the medians from two independent groups along the given axis.

The comparison is performed using the McKean-Schrader estimate of the standard error of the medians.

### Parameters

- group\_1** [array\_like] First dataset. Has to be of size  $\geq 7$ .
- group\_2** [array\_like] Second dataset. Has to be of size  $\geq 7$ .
- axis** [int, optional] Axis along which the medians are estimated. If *None*, the arrays are flattened. If *axis* is not *None*, then *group\_1* and *group\_2* should have the same shape.

### Returns

#### **compare\_medians\_ms**

[[float, ndarray]] If *axis* is *None*, then returns a float, otherwise returns a 1-D ndarray of floats with a length equal to the length of *group\_1* along *axis*.

## scipy.stats.mstats.median\_cihs

`scipy.stats.mstats.median_cihs(data, alpha=0.05, axis=None)`

Computes the alpha-level confidence interval for the median of the data.

Uses the Hettmasperger-Sheather method.

### Parameters

- data** [array\_like] Input data. Masked values are discarded. The input should be 1D only, or *axis* should be set to *None*.
- alpha** [float, optional] Confidence level of the intervals.

**axis** [int or None, optional] Axis along which to compute the quantiles. If None, use a flattened array.

**Returns**

**median\_cihs**  
Alpha level confidence interval.

**scipy.stats.mstats.mjci**

`scipy.stats.mstats.mjci` (*data*, *prob*=[0.25, 0.5, 0.75], *axis*=None)

Returns the Maritz-Jarrett estimators of the standard error of selected experimental quantiles of the data.

**Parameters**

**data** [ndarray] Data array.  
**prob** [sequence, optional] Sequence of quantiles to compute.  
**axis** [int or None, optional] Axis along which to compute the quantiles. If None, use a flattened array.

**scipy.stats.mstats.mquantiles\_cimj**

`scipy.stats.mstats.mquantiles_cimj` (*data*, *prob*=[0.25, 0.5, 0.75], *alpha*=0.05, *axis*=None)

Computes the alpha confidence interval for the selected quantiles of the data, with Maritz-Jarrett estimators.

**Parameters**

**data** [ndarray] Data array.  
**prob** [sequence, optional] Sequence of quantiles to compute.  
**alpha** [float, optional] Confidence level of the intervals.  
**axis** [int or None, optional] Axis along which to compute the quantiles. If None, use a flattened array.

**Returns**

**ci\_lower** [ndarray] The lower boundaries of the confidence interval. Of the same length as *prob*.  
**ci\_upper** [ndarray] The upper boundaries of the confidence interval. Of the same length as *prob*.

**scipy.stats.mstats.rsh**

`scipy.stats.mstats.rsh` (*data*, *points*=None)

Evaluates Rosenblatt's shifted histogram estimators for each data point.

Rosenblatt's estimator is a centered finite-difference approximation to the derivative of the empirical cumulative distribution function.

**Parameters**

**data** [sequence] Input data, should be 1-D. Masked values are ignored.  
**points** [sequence or None, optional] Sequence of points where to evaluate Rosenblatt shifted histogram. If None, use the data.

**6.28.18 Univariate and multivariate kernel density estimation**

---

<code>gaussian_kde(dataset[, bw_method, weights])</code>	Representation of a kernel-density estimate using Gaussian kernels.
----------------------------------------------------------	---------------------------------------------------------------------

---

## scipy.stats.gaussian\_kde

**class** `scipy.stats.gaussian_kde` (*dataset*, *bw\_method=None*, *weights=None*)

Representation of a kernel-density estimate using Gaussian kernels.

Kernel density estimation is a way to estimate the probability density function (PDF) of a random variable in a non-parametric way. `gaussian_kde` works for both uni-variate and multi-variate data. It includes automatic bandwidth determination. The estimation works best for a unimodal distribution; bimodal or multi-modal distributions tend to be oversmoothed.

### Parameters

- dataset** [array\_like] Datapoints to estimate from. In case of univariate data this is a 1-D array, otherwise a 2-D array with shape (# of dims, # of data).
- bw\_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If a scalar, this will be used directly as *kde.factor*. If a callable, it should take a `gaussian_kde` instance as only parameter and return a scalar. If None (default), 'scott' is used. See Notes for more details.
- weights** [array\_like, optional] weights of datapoints. This must be the same shape as dataset. If None (default), the samples are assumed to be equally weighted

### Notes

Bandwidth selection strongly influences the estimate obtained from the KDE (much more so than the actual shape of the kernel). Bandwidth selection can be done by a “rule of thumb”, by cross-validation, by “plug-in methods” or by other means; see [3], [4] for reviews. `gaussian_kde` uses a rule of thumb, the default is Scott’s Rule.

Scott’s Rule [1], implemented as `scotts_factor`, is:

$$n^{**(-1./(d+4))},$$

with *n* the number of data points and *d* the number of dimensions. In the case of unequally weighted points, `scotts_factor` becomes:

$$neff^{**(-1./(d+4))},$$

with *neff* the effective number of datapoints. Silverman’s Rule [2], implemented as `silverman_factor`, is:

$$(n * (d + 2) / 4.)^{**(-1. / (d + 4))}.$$

or in the case of unequally weighted points:

$$(neff * (d + 2) / 4.)^{**(-1. / (d + 4))}.$$

Good general descriptions of kernel density estimation can be found in [1] and [2], the mathematics for this multi-dimensional implementation can be found in [1].

With a set of weighted samples, the effective number of datapoints *neff* is defined by:

$$neff = \text{sum}(\text{weights})^2 / \text{sum}(\text{weights}^2)$$

as detailed in [5].

## References

## Examples

Generate some random two-dimensional data:

```
>>> from scipy import stats
>>> def measure(n):
... "Measurement model, return two coupled measurements."
... m1 = np.random.normal(size=n)
... m2 = np.random.normal(scale=0.5, size=n)
... return m1+m2, m1-m2
```

```
>>> m1, m2 = measure(2000)
>>> xmin = m1.min()
>>> xmax = m1.max()
>>> ymin = m2.min()
>>> ymax = m2.max()
```

Perform a kernel density estimate on the data:

```
>>> X, Y = np.mgrid[xmin:xmax:100j, ymin:ymax:100j]
>>> positions = np.vstack([X.ravel(), Y.ravel()])
>>> values = np.vstack([m1, m2])
>>> kernel = stats.gaussian_kde(values)
>>> Z = np.reshape(kernel(positions).T, X.shape)
```

Plot the results:

```
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots()
>>> ax.imshow(np.rot90(Z), cmap=plt.cm.gist_earth_r,
... extent=[xmin, xmax, ymin, ymax])
>>> ax.plot(m1, m2, 'k.', markersize=2)
>>> ax.set_xlim([xmin, xmax])
>>> ax.set_ylim([ymin, ymax])
>>> plt.show()
```

### Attributes

<b>dataset</b>	[ndarray] The dataset with which <i>gaussian_kde</i> was initialized.
<b>d</b>	[int] Number of dimensions.
<b>n</b>	[int] Number of datapoints.
<b>neff</b>	[int] Effective number of datapoints. New in version 1.2.0.
<b>factor</b>	[float] The bandwidth factor, obtained from <i>kde.covariance_factor</i> , with which the covariance matrix is multiplied.
<b>covariance</b>	[ndarray] The covariance matrix of <i>dataset</i> , scaled by the calculated bandwidth ( <i>kde.factor</i> ).
<b>inv_cov</b>	[ndarray] The inverse of <i>covariance</i> .

### Methods

<code>evaluate(points)</code>	Evaluate the estimated pdf on a set of points.
<code>__call__(points)</code>	Evaluate the estimated pdf on a set of points.
<code>integrate_gaussian(mean, cov)</code>	Multiply estimated density by a multivariate Gaussian and integrate over the whole space.
<code>integrate_box_1d(low, high)</code>	Computes the integral of a 1D pdf between two bounds.
<code>integrate_box(low_bounds, high_bounds[, maxpts])</code>	Computes the integral of a pdf over a rectangular interval.
<code>integrate_kde(other)</code>	Computes the integral of the product of this kernel density estimate with another.
<code>pdf(x)</code>	Evaluate the estimated pdf on a provided set of points.
<code>logpdf(x)</code>	Evaluate the log of the estimated pdf on a provided set of points.
<code>resample([size])</code>	Randomly sample a dataset from the estimated pdf.
<code>set_bandwidth([bw_method])</code>	Compute the estimator bandwidth with given method.
<code>covariance_factor()</code>	Computes the coefficient ( <i>kde.factor</i> ) that multiplies the data covariance matrix to obtain the kernel covariance matrix.

### scipy.stats.gaussian\_kde.evaluate

`gaussian_kde.evaluate(points)`  
 Evaluate the estimated pdf on a set of points.

#### Parameters

**points** [(# of dimensions, # of points)-array] Alternatively, a (# of dimensions,) vector can be passed in and treated as a single point.

#### Returns

**values** [(# of points,)-array] The values at each point.

#### Raises

##### ValueError

2550 [if the dimensionality of the input points is different than] the dimensionality of the KDE. **Chapter 6. API Reference**

### scipy.stats.gaussian\_kde.\_\_call\_\_

`gaussian_kde.__call__(points)`

**scipy.stats.gaussian\_kde.integrate\_gaussian**`gaussian_kde.integrate_gaussian` (*mean, cov*)

Multiply estimated density by a multivariate Gaussian and integrate over the whole space.

**Parameters**

**mean** [array\_like] A 1-D array, specifying the mean of the Gaussian.  
**cov** [array\_like] A 2-D array, specifying the covariance matrix of the Gaussian.

**Returns**

**result** [scalar] The value of the integral.

**Raises****ValueError**

If the mean or covariance of the input Gaussian differs from the KDE's dimensionality.

**scipy.stats.gaussian\_kde.integrate\_box\_1d**`gaussian_kde.integrate_box_1d` (*low, high*)

Computes the integral of a 1D pdf between two bounds.

**Parameters**

**low** [scalar] Lower bound of integration.  
**high** [scalar] Upper bound of integration.

**Returns**

**value** [scalar] The result of the integral.

**Raises****ValueError**

If the KDE is over more than one dimension.

**scipy.stats.gaussian\_kde.integrate\_box**`gaussian_kde.integrate_box` (*low\_bounds, high\_bounds, maxpts=None*)

Computes the integral of a pdf over a rectangular interval.

**Parameters**

**low\_bounds** [array\_like] A 1-D array containing the lower bounds of integration.  
**high\_bounds** [array\_like] A 1-D array containing the upper bounds of integration.  
**maxpts** [int, optional] The maximum number of points to use for integration.

**Returns**

**value** [scalar] The result of the integral.

**scipy.stats.gaussian\_kde.integrate\_kde**`gaussian_kde.integrate_kde` (*other*)

Computes the integral of the product of this kernel density estimate with another.

**Parameters**

**other** [gaussian\_kde instance] The other kde.

**Returns**

**value** [scalar] The result of the integral.

**Raises**

**ValueError**  
If the KDEs have different dimensionality.

**scipy.stats.gaussian\_kde.pdf**

`gaussian_kde.pdf(x)`  
Evaluate the estimated pdf on a provided set of points.

**Notes**

This is an alias for `gaussian_kde.evaluate`. See the `evaluate` docstring for more details.

**scipy.stats.gaussian\_kde.logpdf**

`gaussian_kde.logpdf(x)`  
Evaluate the log of the estimated pdf on a provided set of points.

**scipy.stats.gaussian\_kde.resample**

`gaussian_kde.resample(size=None)`  
Randomly sample a dataset from the estimated pdf.

**Parameters**

**size** [int, optional] The number of samples to draw. If not provided, then the size is the same as the effective number of samples in the underlying dataset.

**Returns**

**resample** [(self.d, size) ndarray] The sampled dataset.

**scipy.stats.gaussian\_kde.set\_bandwidth**

`gaussian_kde.set_bandwidth(bw_method=None)`  
Compute the estimator bandwidth with given method.

The new bandwidth calculated after a call to `set_bandwidth` is used for subsequent evaluations of the estimated density.

**Parameters**

**bw\_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If a scalar, this will be used directly as `kde.factor`. If a callable, it should take a `gaussian_kde` instance as only parameter and return a scalar. If None (default), nothing happens; the current `kde.covariance_factor` method is kept.

**Notes**

New in version 0.11.

## Examples

```
>>> import scipy.stats as stats
>>> x1 = np.array([-7, -5, 1, 4, 5.])
>>> kde = stats.gaussian_kde(x1)
>>> xs = np.linspace(-10, 10, num=50)
>>> y1 = kde(xs)
>>> kde.set_bandwidth(bw_method='silverman')
>>> y2 = kde(xs)
>>> kde.set_bandwidth(bw_method=kde.factor / 3.)
>>> y3 = kde(xs)
```

```
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots()
>>> ax.plot(x1, np.ones(x1.shape) / (4. * x1.size), 'bo',
... label='Data points (rescaled)')
>>> ax.plot(xs, y1, label='Scott (default)')
>>> ax.plot(xs, y2, label='Silverman')
>>> ax.plot(xs, y3, label='Const (1/3 * Silverman)')
>>> ax.legend()
>>> plt.show()
```

**scipy.stats.gaussian\_kde.covariance\_factor**

`gaussian_kde.covariance_factor()`

Computes the coefficient (*kde.factor*) that multiplies the data covariance matrix to obtain the kernel covariance matrix. The default is `scotts_factor`. A subclass can overwrite this method to provide a different method, or set it through a call to `kde.set_bandwidth`.

**6.28.19 Warnings used in `scipy.stats`**

<code>PearsonRConstantInputWarning(msg)</code>	Warning generated by <code>pearsonr</code> when an input is constant.
<code>PearsonRNearConstantInputWarning(msg)</code>	Warning generated by <code>pearsonr</code> when an input is nearly constant.

### scipy.stats.PearsonRConstantInputWarning

**exception** `scipy.stats.PearsonRConstantInputWarning(msg=None)`  
 Warning generated by `pearsonr` when an input is constant.

**with\_traceback()**  
 Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

### scipy.stats.PearsonRNearConstantInputWarning

**exception** `scipy.stats.PearsonRNearConstantInputWarning(msg=None)`  
 Warning generated by `pearsonr` when an input is nearly constant.

**with\_traceback()**  
 Exception.with\_traceback(tb) – set self.\_\_traceback\_\_ to tb and return self.

For many more stat related functions install the software R and the interface package rpy.

## 6.29 Low-level callback functions

Some functions in SciPy take as arguments callback functions, which can either be python callables or low-level compiled functions. Using compiled callback functions can improve performance somewhat by avoiding wrapping data in Python objects.

Such low-level functions in SciPy are wrapped in `LowLevelCallable` objects, which can be constructed from function pointers obtained from ctypes, cffi, Cython, or contained in Python `PyCapsule` objects.

<code>LowLevelCallable</code>	Low-level callback function.
-------------------------------	------------------------------

### 6.29.1 scipy.LowLevelCallable

**class** `scipy.LowLevelCallable`  
 Low-level callback function.

**Parameters**

- function** `[[PyCapsule, ctypes function pointer, cffi function pointer]]` Low-level callback function.
- user\_data** `[[PyCapsule, ctypes void pointer, cffi void pointer]]` User data to pass on to the callback function.
- signature** `[str, optional]` Signature of the function. If omitted, determined from `function`, if possible.

**Notes**

The argument `function` can be one of:

- `PyCapsule`, whose name contains the C function signature

- ctypes function pointer
- cffi function pointer

The signature of the low-level callback must match one of those expected by the routine it is passed to.

If constructing low-level functions from a PyCapsule, the name of the capsule must be the corresponding signature, in the format:

```
return_type (arg1_type, arg2_type, ...)
```

For example:

```
"void (double)"
"double (double, int *, void *)"
```

The context of a PyCapsule passed in as `function` is used as `user_data`, if an explicit value for `user_data` was not given.

#### Attributes

- function** Callback function given.
- user\_data** User data given.
- signature** Signature of the function.

#### Methods

---

<code>from_cython(module, name[, user_data, signature])</code>	Create a low-level callback function from an exported Cython function.
----------------------------------------------------------------	------------------------------------------------------------------------

---

#### `scipy.LowLevelCallable.from_cython`

**classmethod** `LowLevelCallable.from_cython(module, name, user_data=None, signature=None)`

Create a low-level callback function from an exported Cython function.

#### Parameters

- module** [module] Cython module where the exported function resides
- name** [str] Name of the exported function
- user\_data** [{PyCapsule, ctypes void pointer, cffi void pointer}, optional] User data to pass on to the callback function.
- signature** [str, optional] Signature of the function. If omitted, determined from `function`.

#### See also:

Functions accepting low-level callables:

`scipy.integrate.quad`, `scipy.ndimage.generic_filter`, `scipy.ndimage.generic_filter1d`, `scipy.ndimage.geometric_transform`

Usage examples:

*Extending `scipy.ndimage` in C, Faster integration using low-level callback functions*
